HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

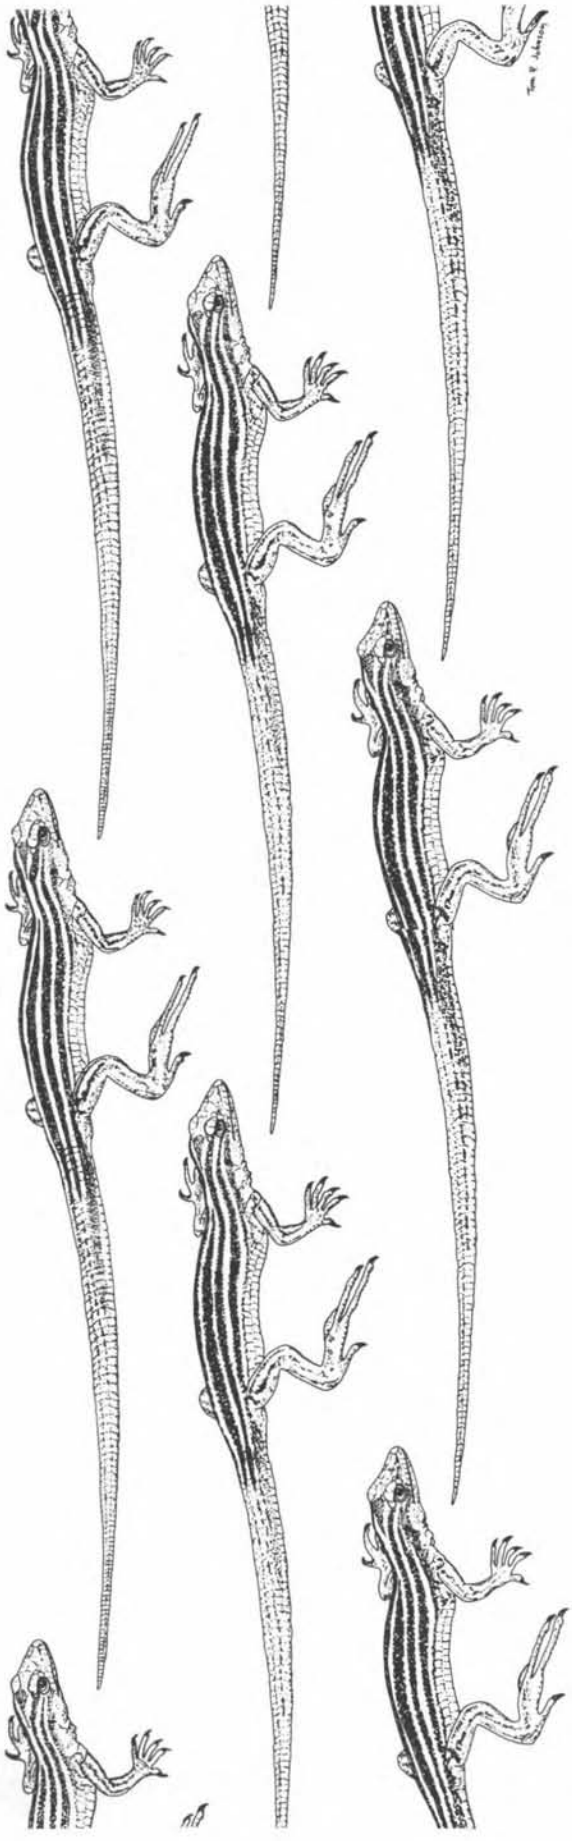
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars**, and several **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$12.00
Regular member	$15.00
Sustaining member	$20.00
Contributing member	$25.00
Institutional	$25.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

ANNUAL MEETING

The 24th Annual Meeting of
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
AND
The 29th Annual Meeting of
THE HERPETOLOGISTS' LEAGUE
will be hosted by
MEMPHIS STATE UNIVERSITY
Memphis, Tennessee
9-14 August 1981

FEATURED SYMPOSIUM: Reproductive Biology of Reptiles

PROGRAM SUMMARY:

Sunday, 9 August	Registration; SSAR Board of Directors Meeting; HL Board of Trustees Meeting; Fifth Annual SSAR Regional Herpetological Societies Conference
Monday, 10 August	HL Distinguished Herpetologists Lecture by Ernest Williams; Contributed Papers; Poster Session; Symposium on Reproductive Biology of Reptiles; SSAR/HL Liaison Committee Meeting; Herp Art Exhibit; Commercial Exhibitors' Display; Social
Tuesday, 11 August	Contributed Papers; Poster Session; Symposium on Reproductive Biology of Reptiles; Herp Art Exhibit; Live Herp Exhibit; Commercial Exhibitors' Display; SSAR Business Meeting; Barbecue at Schlitz Belle
Wednesday, 12 August	Contributed Papers; Poster Session; Symposium on Reproductive Biology of Reptiles; Herp Art Exhibit; Live Herp Exhibit; HL Business Meeting; Riverboat Dinner Cruise
Thursday, 13 August	Contributed Papers; Poster Session; Herp Art Exhibit; Live Herp Exhibit
Friday, 14 August	Live Herp Exhibit; Tour of Memphis Zoo and Aquarium

GENERAL INFORMATION:

Pre-registration forms, including the call for papers and other information, will be mailed to members of the two societies in March 1981. Copies of the meeting information will be sent on request to interested persons. The deadline for receipt of abstracts will be 5 June 1981. A regular pre-registration fee of $25, or a student fee of $15, will be due *no later than 5 June 1981*. The regular registration fee at the meeting will be $30, with a student fee of $20.

Housing in an air-conditioned dormitory will be available at $10.20 per person per day for double occupancy (4 sharing bath); $16.80 per person per day for single occupancy (2 sharing bath); or $24 per day for a family (only) suite consisting of two rooms (4 beds) with a connecting bath.

Transportation: Individuals planning to travel by air should make reservations into Memphis International Airport. A shuttle to campus will be provided. Camping facilities are available in the Memphis area.

Special Activities: Spouse and family trips to Libertyland Amusement Park, Chucalissa Indian Museum, Memphis Pink Palace Museum, Brooks Memorial Art Gallery, or Memphis Botanical Gardens may be organized depending on interest. Daytime child care facilities may be available if there is sufficient demand.

LOCAL COMMITTEE CHAIRMAN:

James S. Jacob
Ecological Research Center
Department of Biology
Memphis State University
Memphis, TN 38152
(901) 454-2588 or 2581

SSAR BUSINESS

SSAR ELECTION RESULTS

Six hundred and seventy-four SSAR members responded to the mail ballot to elect SSAR officers for calendar 1981. The following individuals were elected:

President-elect:	Kraig Adler
Secretary:	Joseph T. Collins
Treasurer:	Henri C. Seibert
Board of Directors:	Max A. Nickerson
(Class of 1983)	Marvalee Wake

It is of interest to note that Richard Nixon and Bert Lance each received one write-in vote for the offices of secretary and treasurer, respectively. However, neither is eligible for SSAR office since they are not SSAR members.

The SSAR thanks all candidates for accepting the nomination to run for SSAR office. In addition, the Society is grateful to Jerry D. Johnson, El Paso Community College, for ably serving as SSAR elector for 1980. ●

REPORT OF THE SSAR COMMITTEE ON COMMON AND SCIENTIFIC NAMES FOR 1980

This report is the third annual update prepared by the SSAR Committee on Common and Scientific Names for North American amphibians and reptiles (north of Mexico). This report (and future reports) is compiled to fulfill the charge to our committee to keep the herpetological community informed of published taxonomic shifts and new descriptions, and to propose or record new common names brought about by same. In addition, this third update permits us to record recent changes overlooked and not included in "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (Collins *et al.*, 1978).

The proposed changes and taxonomic shifts listed below are in order as they appear in our list (Collins *et al.*, 1978).

PAGE 14, genus *Chrysemys:* Pritchard (1979) and Vogt and McCoy (1980) proposed reviving the generic name *Pseudemys* for all species listed under the genus *Chrysemys* except *C. picta*. The common names for the affected species and subspecies remain the same. The genus *Pseudemys* assumes the common name "Basking Turtles," while the monotypic genus *Chrysemys* assumes the common name "Painted Turtles."

PAGE 14, genus *Chrysemys:* Fahey (1980) proposed that *Chrysemys concinna* be placed in the synonymy of *Chrysemys floridana*. The common name for *C. floridana* remains "Cooter." Fahey (1980) did not address the status of the subspecies of this complex, but acceptance of his proposed synonymy for the two species involved would require careful re-examination of the status of all races currently recognized.

PAGE 18, genus *Anolis:* Schwartz and Thomas (1975) proposed that *Anolis carolinensis* is monotypic. The common name remains the same.

PAGE 28, genus *Elaphe:* Olson (1977) proposed that *Elaphe obsoleta bairdi* be elevated to specific status. The common name remains the same.

PAGE 31, genus *Nerodia:* Blaney and Blaney (1979) proposed that *Nerodia fasciata* be placed in the synonymy of *N. sipedon*. The common name for *N. sipedon* becomes "Banded Water Snake." The common name for the subspecies *N. f. fasciata* (which would become *N. s. fasciata*) becomes "Southern Water Sanke." Schwaner, Dessauer and Landry (1980) disagreed with Blaney and Blaney (1979), and, by inference, proposed that *N. sipedon* and *N. fasciata* be recognized as species, their current status.

PAGE 35, line 13: Rossman (1979) proposed the elimination of the subspecies *Thamnophis elegans biscutatus* on the basis that it represented an intergrade population between *T. e. vagrans* and *T. e. elegans*. Fitch (1980) disagreed with Rossman (1979) and recommended that *T. e. biscutatus* be recognized as a valid subspecies.

PAGE 36, line 5: Benton (1980) proposed the elimination of the subspecies *Thamnophis sirtalis semifasciatus*.

ARTHUR LOVERIDGE 1891-1980

Arthur Loveridge was one of those rare and exceedingly fortunate persons who are able to spend virtually their entire lives doing what they like best. His life-long enthusiasm for natural history was kindled during his boyhood in South Wales where he was born at Penarth, Glamorganshire, on 28 May 1891, the tenth of eleven children. Like many a lad he caught beetles, pursued butterflies, then graduated to birds, small mammals, and adders, but, unlike most, he soon had a large personal museum that he curated and documented with meticulous care. He attended the University of South Wales, and served on the staffs of the museum at Manchester University and the National Museum of Wales. In 1914 he applied for and received the curatorship of the natural history museum in Nairobi, British East Africa, a position that must have seemed like paradise to a young naturalist. Although he found the collections in chaos, he attacked the problem of setting them in order with vigor and enthusiasm and soon began acquiring a steady stream of new specimens.

In 1915 Loveridge joined the East African Mounted Rifles whose objective was to clear the enemy from neighboring German East Africa. Patriotism may have been a factor, but the campaign also offered an opportunity to be in the field for months at a time and to learn firsthand about the fauna of a fascinating part of the world. His interests immediately became known to his brothers-in-arms, and he was perpetually on call to catch any animal, often a venomous snake, that had invaded someone's tent. He was constantly collecting, plucking beetles from bushes and popping them into his killing bottle even while under enemy sniper fire, bagging reptiles of all kinds, and salvaging a wide variety of wildlife caught or killed in the field or camp. He and his personally trained native helpers often worked far into the night preparing and poisoning (with arsenic) his specimens for later shipment to Nairobi. Through it all he maintained a small zoo, and because of the exigencies necessitated by having to improvise cages from the scant materials at hand, escapes were common and so was the excitement engendered when the truants were found on the prowl. Loveridge's influence was manifested in many ways. A regiment waited while a chameleon was photographed on a rifle; he borrowed the general's car and chauffeur to rescue a collection of preserved snakes from an abandoned German's house; and once he prompted his sergeant to demand, "Is this a war or a blooming museum expedition?"

When the campaign was over he continued his operations in and out of the Nairobi Museum until 1921, when he became an assistant game warden in the former German territory, then called Tanganyika, where he was in the field protecting big game from poachers and was often called upon to trap or gun down lions that had killed or injured tribesmen. He was fearless and no doubt one of the Game Department's most valued employees.

Loveridge was always resourceful, an asset that carried him through numerous tight spots during his many years of field work. An amusing example of his ingenuity occurred when he returned to his base in the far interior and was handed a telegram asking him to be in Mombasa, Kenya, in less than a week to meet his fiancée and be married by her uncle who was coming from Scotland for the occasion. Hurriedly he sought emergency leave, packed his gear and transported it halfway across Tanganyika by rail, and then caught the twice-weekly train to Dar es Salaam on the coast. The ship he had hoped to board had left an hour before his arrival and another was not due for a fortnight. Nothing daunted he virtually commandeered a sailing dhow to take him to the island of Zanzibar, fifty miles away, where ocean-going vessels were more apt to call. He rounded up the score of passengers who had not expected to leave until the following day, expedited their passage through the local health and other official formalities, and hired a tug to tow the dhow through the winding harbor channel to open water. With sails set, progress was excellent at first, but they were soon becalmed on the wrong side of Zanzibar. Loveridge talked the captain into having him rowed ashore where he hiked through a downpour to the nearest telephone, summoned a taxi, and soothed the customs officer who was perturbed by his unauthorized landing. Such singleness of purpose deserved its reward. A French liner arrived unexpectedly the next day and Loveridge landed at Mombasa in ample time to wed his fiancée, Mary Sloan, whom he affectionately called Queenie.

In 1924 the Loveridges and their small son sailed for the United States where Arthur became associated with Harvard's Museum of Comparative Zoology, and where he served with distinction until his retirement in June, 1957. He not only curated the large collection Thomas Barbour had assembled, but he added impressively to it on his own, chiefly as the result of five long expeditions he made during the period from 1926 to 1949, inclusive, to the forested regions of East Africa in (by their names at the time) Kenya, Nyasaland, Tanganyika, Tete in Mozambique, and Uganda. Mrs. Loveridge and their son, Brian, accompanied him on some of those trips, reports about which appeared in bulletins of the Museum of Comparative Zoology.

Loveridge was a prolific scientific writer, and he published approximately 180 herpetological papers, the last of which appeared in 1979. Among them were an important series of taxonomic revisions of African genera and families and a check list of the amphibians and reptiles of East Africa. Harvard University Press published a bibliography of his contributions (1913-1936, 1937-1944, 1944-1950), and he continued the list (1951-1958, 1958-1977) privately, the printing being done on St. Helena Island.

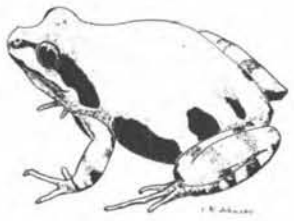
Unlike many professional zoologists who

consider it infradig to impart their knowledge to the lay public, Loveridge was a skillful popular writer. He began by submitting short articles to natural history magazines. Later he wrote a series of highly readable books variously titled "Many Happy Days I've Squandered," "Tomorrow's a Holiday," "I Drank the Zambezi," and "Forest Safari," which were filled with wry humor, and even the most hair-raising experiences were recounted with no attempt at the dramatic.

Loveridge and his "Queenie" retired to the island of St. Helena in the South Atlantic Ocean in 1957, where he remained active, publishing a number of short notes about local wildlife and completing several longer contributions. He also conducted a vast correspondence with friends and colleagues, with each letter logged by number; the last one mailed to me, in late 1979, was No. 6812! Because we were both good correspondents, I learned to know Loveridge better when he was far away than when he had been at Harvard. We kept each other informed about our activities, we waxed philosophical at times, and I, fortunately, was able to find the various references he needed and to answer his many questions. Also, in support of a hobby that began when he was a boy, I sent him a steady flow of postage stamps from my incoming mail, adding as many stamps as possible to each letter without exceeding the weight allowed by the post office.

He made a number of trips to England during his long retirement and, because St. Helena is a volcanic peak with no room for an airport, passage was by motorship. Sailings by the two vessels which touched at St. Helena were at infrequent intervals, and once he had a lengthy delay in Britain, waiting for a return passage, after one of the ships sustained a severe fire at sea and the passengers were forced to take to the lifeboats.

Despite all the "roughing it" that Arthur Loveridge did during so many decades, he remained the proper Englishman with his professional colleagues. I well recall that, at a small farewell luncheon at Harvard, he announced the time had come for us to drop formality. "Hereafter," he said, "I'm going to call you Conant." And so it was for many years until we imperceptibly switched to a first name basis.



Mrs. Loveridge died suddenly in June, 1972, after picking vegetables in their garden. Four years later Brian moved to St. Helena to be with his father.

Loveridge's mind remained clear almost until the day of his death. Just a few months previously he announced his discovery that two names, used by entomologists, one for a family and another for a genus, were identical with or very similar to names long employed by herpetologists. He asked me if I would like to appeal to the International Commission on Zoological Nomenclature for a decision to emend the duplication. I turned the problem over to Hobart M. Smith who is following through and using Loveridge's name as co-author.

Arthur Loveridge accomplished much during his long life. He saw Africa when it was far more primitive than it is today and recorded innumerable facts for posterity. Few other persons of his generation collected and carefully preserved as much museum material as he did. His knowledge was truly phenomenal and, although he concentrated in the field on reptiles and amphibians, his contributions, in the way of specimens, to other disciplines were substantial. He was a quiet, humble gentleman who was always friendly, cooperative, and thoughtful. He favored me with copies of his papers, even when he had few to distribute, because he felt they might be useful to a zoo curator who would be expected to identify specimens from Africa that might arrive unexpectedly. They did indeed, before the rules were changed and nothing could be imported without a permit.

Loveridge's visits to England were memorable events to his many friends and relatives who eagerly looked forward to seeing him and enjoying his cheerful presence. He was a highly respected friend and naturalist who is mourned by many. He died in the St. Helena General Hospital on 16 February 1980 after a short illness at the age of almost 89.

FIRST REPTILE BREEDING CERTIFICATE NOMINATIONS RECEIVED

Nominations have been submitted to the AAZPA Honors and Awards Committee from the institutions listed below for recognition as the first zoological facility in North America to have bred the designated species in captivity:

Woodland Park Zoological Gardens
Osteopelus dominicanus, January 1978
Oklahoma City Zoo
Lampropeltis getulus nigritus, 7 August 1975; *Chelodina longicollis*, 21 April 1975
Dallas Zoo

FEDERAL REGULATIONS FOR THE IMPORTATION OF ANTIVENIN

There appears to be some confusion among AAZPA institutions in regard to the proper method for importing antivenins.

Two Federal Agencies are involved in the importation of antivenin, namely the Department of Health and Human Services, and the Department of Agriculture.

The Department of Health and Human Services requires an Investigational New Drug filing to permit the importation of snake antivenins into this country.

Such antivenins for human use are subject to Section 262 of Title 42 of the U.S. Code which prohibits the sending, carrying, or bringing for sale, barter, or exchange from any State or possession into any other State or possession or from any foreign country into any State or possession any biologic product unless manufactured at an establishment holding an unsuspended and unrevoked license issued by the Secretary of Health and Human Services.

The antivenin products you wish to import have not been prepared at a U.S. licensed establishment nor have any licenses been

issued to any manufacturer for such products.

Since zoos and possibly a few other institutions maintain species of snakes for which no licensed antivenin products are available, they recognize the importance for such institutions to have antivenins available in the event someone is bitten by a snake. They therefore will permit importation provided the zoo's physician or its medical consultant will submit the following information to the Director, Bureau of Biologics as an Investigational New Drug application (IND):

1. The name of each product, the name and address of the manufacturer, the type of snake(s) against whose venom the antivenin is claimed to be effective and, when available, the lot numbers(s) of the product, together with a statement by the manufacturer that the antivenin has passed the applicable safety and sterility tests. One method of accomplishing this is by having the statement typed across the invoice sheet. The lot number and safety and sterility test results can be submitted upon receipt of the antivenin.
2. A statement that the antivenin is being imported solely as an emergency measure in the event that an employee of the institution is bitten and that the product will not be resold.
3. A statement that the antivenin will be maintained under the physician's control and only administered under his supervision.
4. A statement to the effect that, in the event such product is administered, a complete case report will be submitted to this Bureau.

Upon receipt of the above information, appropriate steps will be taken to assist in clearing the material through customs.

If additional information is required please contact:

Harry M. Meyer, Jr., M.D.
Director
Bureau of Biologics
Food and Drug Administration
8800 Rockville Pike
Bethesda, MD 20205

The Department of Agriculture, Animal and Plant Health Inspection Service (APHIS) requires that two copies of Veterinary Services Form 16-3 (Application For Veterinary Permit To Import Or Transport Organisms Or Vectors) be submitted to its Hyattsville, Maryland office. The reason for this is the equine origin of antivenins. Upon approval of the permit application, APHIS will issue the importing institution a red tag(s) which you in turn send to the foreign manufacturer to be affixed to the package prior to shipment to the United States.

SUMMARY OF STEPS TO BE TAKEN WHEN IMPORTING ANTIVENIN

A. Apply to Bureau of Biologics for an institutional BB-IND number. This number is ongoing and the foreign manufacturers should include it on all shipping labels.
B. Request permission from the Bureau of Biologics for each separate importation, submitting to them the information required in numbers one through four above. Remember your BB-IND number is ongoing and should appear on all correspondence to the Bureau.
C. Upon each importation, apply to APHIS for a permit to import antivenin, and when permit is approved send red tag(s) to foreign manufacturer prior to shipment of product.

Finally, it is important to remember that, in the event any foreign antivenin is used clinically, a complete case report must be submitted to the Bureau of Biologics.

A BICEPHALIC *CROTALUS HORRIDUS* FROM ALABAMA

A two-headed timber rattlesnake *(Crotalus horridus)* was born in captivity on October 24, 1978 (Figure 1). The adult female was collected in Bullock County, Alabama during the Spring of 1978. The litter consisted of five fully developed young and three undeveloped (infertile) eggs. Two of the young, including the bicephalic specimen, were dead when discovered in the cage. One has subsequently died, while the remaining two are alive at the time of this writing.

Klauber (1956) cited reports of the occurrence of bicephaly in several species of rattlesnakes including *C. b. basiliscus, C. d. terrificus, C. v. oreganus, C. v. viridis, C. horridus, C. adamanteus,* and what he believed was a *C. s. scutulatus* plus several others in which the rattlesnake was not identified. Murphy and Shadduck (1978) recorded a bicephalic *C. adamanteus* born to a female from the mating of a captive pair. They also reported accounts of the condition in *Sistrurus m. streckeri, C. atrox* and a "swamp rattlesnake" from Wisconsin.

Figure 1. A bicephalic *Crotalus horridus atricaudatus* born in captivity to a wild caught female from Bullock County, Alabama in 1978.

Figure 2. Dorsal view of the anterior portion of a bicephalic *C. h. atricaudatus* from Alabama.

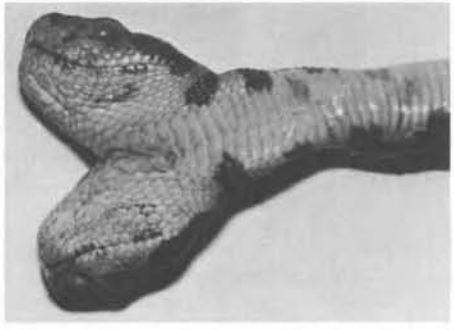

Figure 3. Ventral view of the anterior portion of a bicephalic *C. h. atricaudatus* from Alabama.

The two-headed specimen reported here is joined just behind the most posterior labials, at the angle of the jaw, leaving the two mouths independently functional (Figure 2). Ventrally, the connection is at the first ventral scute (Figure 3).

Except for the absence of the left eye on the right head (Figure 1 and 2), a condition also observed in one of the snake's siblings, both heads appear to be normal.

This individual is a 260 mm male with 23 scale rows at midbody. Other counts were: ventrals 169; subcaudals 25; supralabials, right head 14-12, left head 14-13; infralabials, right head 16-15, left head 16-15. Where two numbers are given, the first is for the right side of the head.

AN INSTANCE OF NATURAL CANNIBALISM BY *UMA N. NOTATA* BAIRD

Numerous articles have been published describing cannibalism by many species of lizards in both field and cage environments. Most concern members of the Family Iguanidae (Bowie, 1973; Burt, 1928; Carpenter, 1963; Grove, 1971; Johnson, 1965; Kennedy, 1956; Knowlton, 1934; Knowlton and Thomas, 1934; Montanucci, 1965; Mosley, 1963; Shaw, 1950; Smith and Fritts, 1969), though the Scincidae (Douglas, 1965) and Varanidae (Burden, 1928; Johnson, 1976) were also noted as cannibalistic. In general, these lizards can be described as aggressive predatory animals. The number of references and the diverse species indicates to us that cannibalism is not an aberrant isolated occurrence in lizard populations. We present here another instance of cannibalism by a free-living lizard.

At about 12:30 p.m. on April 12, 1971, a clear, calm day, the senior author and his brother found a sidewinder, *Crotalus cerastes*, which was biting an adult *Uma notata notata* by the base of the tail. The snake released the lizard, which died a few hours later, and retreated down a hole at the base of a bush. The location is in the Algodones Dunes about 13½ road miles east of the intersection of California Highways 111 and 78 in Brawley, Imperial County, California. Only the lizard was collected.

Prior to skeletonizing the lizard, the junior author opened the body cavity to determine sex. On probing the viscera, a conspecific juvenile was found in the esophagus. The adult was a male with a snout to vent length of 100 mm, and the juvenile was also a male with a snout to vent length of 51 mm. The smaller one had been swallowed head first; it was virtually intact, missing patches of skin from the top of its head and shoulders, and it had numerous adherent sand grains. Both have been skeletonized and are in the junior author's disarticulated skeleton collection.

Carpenter (1963) reported that *Uma* ate conspecific juveniles. Shaw (1950) observed that *Uma n. notata* captured in Imperial County, as was our specimen, were cannibalistic in an enclosure. Animals approximately the same size as our animal ate juveniles about one-half their size. According to Shaw, the prey was normally seized head first, its skull crushed by repeated chewing and then ingested head first. The anterior abrasions on our juvenile animal indicate that it was probably captured and ingested as described above.

Fox (1975) described cannibalism as intraspecific predation that should be thought of as a normal phenomenon occurring in many natural populations as well as in the laboratory. According to Fox (1975), fishes, anurans, birds, mammals and many invertebrate species exhibit cannibalism. In natural populations, cannibalism could offer a number of advantages for a predator by eliminating a potential competitor for natural resources. Therefore, in lizards cannibalism could be a mechanism for stabilizing a population and reducing competition.

VOCALIZATIONS BY THE MEXICAN HYLID FROG *HYLA TAENIOPUS*

Duellman (1970) stated that: "*Hyla taeniopus* has not been heard to call in the field; recordings of the call are not available. One individual kept in captivity uttered one loud groan-like note. On the basis of this one observation and the presence of vocal slits, it may be assumed that this species does possess a voice. However, the significance of the voice in mating behavior is quite questionable."

Consequently the following observations are of some interest:

30 January 1977, 2:00 A.M. A captive male *Hyla taeniopus* collected the previous spring near Tezuitlan, Puebla, Mexico, gave a series of 10 sequences of calls that I describe as a nasal "wan wan wan", etc. Each sequence was 2-3 seconds in length and all were given in a period of one minute. Further calls were heard on 23 February 1977 (9:30 A.M.), 24 February 1977 (4:45 A.M.), 28 February 1977 (8:50 A.M.) and 13 March 1977 (8:30 A.M.).

I have maintained the *Hyla taeniopus* in captivity since 14 April 1976, and the calls described above are the only ones of that type heard since that time. The period during which they were given coincides closely with the breeding season for the frog as suggested by Duellman (1970), who believed breeding occurs from December through February. Thus, it is possible that this call functions as a mating call.

On 21 March 1977, another type of vocalization was given by the tree frog. The call was given when I picked the frog up by the waist. This call was similar to the "wan wan" call but lower in volume, and may function as a releaser to discourage other male frogs from attempting amplexus.

A LARGE EGG CLUTCH FROM AN EASTERN HOGNOSE SNAKE, *HETERODON PLATYRHINOS*

On 19 June, 1979, an eastern hognose *(Heterodon platyrhinos)* at the Cincinnati Museum of Natural History laid 49 eggs, an unusually large number for the species.

The mother had been caught about dusk on 14 May, 1979, near the westernmost edge of Cincinnati, Hamilton County, Ohio. Her length at the time of laying was 0.97m.

The last egg was laid about 9 A.M. The following measurements were completed within one-half hour after the last egg was laid; they are listed in order from maximum length to minimum length, the order of laying being unknown:

	Length (cm)	Diameter (cm)
1)	3.70	1.97
2)	3.60	2.11
3)	3.60	2.02
4)	3.60	1.98

HANDLER BEWARE! LARGE CONSTRICTORS CAN KILL!

On 19 September, 1978, an amateur herpetologist in Florence, Kentucky, was killed by a python from his collection. The main purpose of this note is to reëmphasize the danger inherent in the handling of large constricting snakes.

The data presented here came from five sources: Donald W. Stith, the Coroner of Boone County, Kentucky; Dr. Robert J. Ritterhoff, the Deputy Coroner of Hamilton County, Ohio; the wife and son of the victim; members of the Greater Cincinnati Herpetological Society who cared for the victim's animals after the misfortune; and personal observations as one of those members.

The victim was a well-developed, well-nourished, male Caucasian aged 33. He was nearly 1.7 m tall and weighed about 77kg. At the time of death, he had not been under any physician's care for a considerable period, nor did he seem to have had any reason to have been. He had been handling reptiles for at least four or five years, was a member of the Greater Cincinnati Herpetological Society, and was known locally as a person who did a good job of giving reptile programs to school groups, Scout troops, *etc.*

The snake was a female reticulated python, *Python reticulatus* (Schneider, 1801), nearly 4m long, 37cm in girth, and about 23kg in weight. The snake had been in the victim's possession for about one year. It was housed with a slightly larger female of the same species in a cage 1.2 x 2.4m by 1.2m high; one long side of the cage consisted of two sliding glass doors.

When last seen by his spouse, the victim was preparing to feed some of his animals. As she walked up the stairs out of the basement, he was opening a cage containing Burmese pythons and other snakes. To free his hands he had tucked a dead rabbit under his chin.

A while later, the victim's family heard a crash downstairs, but the basement was cluttered, and crashes weren't at all unusual when someone was down there. Some time later, (five or ten minutes?) they noticed they'd heard nothing for a while. When the basement door was opened, the victim was found collapsed on the landing with the snake wrapped around his neck, shoulders, and upper arms. The victim's wife unwrapped the snake, which offered little resistance, but attempts to revive the victim were in vain. He was pronounced dead at 11 P.M., death apparently having occurred at about 10:25.

The coroner was called at 10:50 P.M. When he arrived, the neck of the victim was distinctly white; the face from the chin up was red; the trunk was of normal color. There was bleeding from the right ear, but not the left, and there had been capillaries burst in the whites of the eyes.

An autopsy was performed the next day by the Deputy Coroner of Hamilton County, Ohio, who is a physician. (Kentucky law does not require that coroners be physicians, and the Boone County Coroner is not one.)

The post-mortem revealed no evidence of heart failure, stroke, *etc.*, which might have caused death. There was no ethyl alcohol in the blood. There was no sign of any debilitating injuries, a blow on the head, for example.

The only wounds on the body were one small mark on the throat and some abrasions on the back of the right hand. On the photographs of the victim, none of these wounds appears to be from snake-bite. The victim's thyroid and hyoid cartilages were intact.

The death certificate lists death as accidental and due to asphyxia as a result of neck constriction by a python snake.

In conclusion, I would like to warn handlers of large constricting snakes to guard against over-confidence in dealing with these animals. No matter how much of a "he-man" you are, don't handle large snakes alone. Perhaps even more important, those in the education profession should take special care to alert would-be and novice snake handlers of the potential dangers of large constrictors.

BILATERAL CLEFT LABIAL AND PALATE IN THE PROGENY OF A *CROTALUS VIRIDIS VIRIDIS* RAFINESQUE

In October, 1978, a wild-bred prairie rattlesnake *(Crotalus viridis viridis)* from the Missouri Breaks region of Northern Montana gave birth to seven siblings, all females. Although morphologically normal in all other external features, bilateral cleft labial and cleft palate was present in six of the seven siblings (Figure 1). The single specimen with normal labials and palate was stillborn. The six females with cleft labial and palate moulted in 7-10 days and continually refused to feed on newborn mice. The specimens were sacrificed at 29 days postpartum and catalogued at the Brigham Young University Life Sciences Museum (#33191-7). The parental female died six days postpartum (respiratory infection).

Each specimen was examined grossly and microscopically at 6x to 32x magnification. All six malformed snakes exhibited similar morphological defects. Each palate was deeply indented and the clefts extended from the anterior margin of the nasal opening, lateral to the rostral, to the internal nares which appeared normal. Each lateral nasal process was bilaterally cleaved giving the appearance of an exaggerated frontonasal area (Figure 1A). The bilateral clefts extended along the entire length of the nasal sacs, passing between the maxilla and the anterior palatine laterally, and the premaxilla and vomer medially. Head width appeared slightly broader, possibly due to the unfused palates. The morphological defects in these speci-

mens appeared similar to defects previously described by Bellairs and Boyd (1957) in *Eunectes murinus* embryos.

Facial clefts are major human congenital malformations and have been investigated extensively as to their etiology (review by Shapiro, 1976). Cleft lip, cleft palate and/or cleft lip combined with cleft palate has also been studied in experimental animals, principally dogs (see Cooper and Mattern, 1971). The three major factors contributing to cleft anomalies seem to be gross chromosomal anomalies, single gene traits and environmental teratogens (Shapiro, 1976; Fogh-Anderson, 1971).

We have no conclusive evidence as to the etiology of this high incidence of cleft anomalies. However, the parental female was the sole survivor of 23 gravid *C. viridis viridis* received June 8, 1978 from the Montana Rattlesnake Company, Wilsall, Montana. These gravid adults had been previously housed communally for four weeks and respiratory infections were obvious (at necropsy) in 21 of the 23 specimens. They also had been electronically stimulated (for venom extraction) an unknown number of times during the initial stages of embryonic development (May). These circumstances provide at least "suggestive", although certainly inconclusive, teratogenic etiology.

We believe this anomaly to be rare in *adult* reptiles. The literature on reptilian cleft labial and/or palate is scant. The only report we found is that by Bellairs and Boyd (1957). Many reptiles are chemically "cued" to food prey items through nasal or vomeronasal stimulation. These necessary processes are possibly disrupted by the cleft abnormalities thereby limiting the number of cleft specimens attaining adulthood. Also, since both cartilaginous nasal capsules are deficient, exposing the nasopalatine ducts and oral cavity internally, the specimens are likely susceptible to bacterial infections.

Bellairs spoke on the subject of reptilian clefts in his keynote address at the Joint Herpetology Conference, Tempe, Arizona (1978). He requested that the herpetological community become aware of the lack of information regarding this unique anomaly in reptiles and suggested that all occurrences be communicated to the literature. This report is submitted with Bellairs's comments in mind.

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1981 Grants-In-Herpetology Program. This program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. Grant proposals will be considered in the following areas:

1) **HERPETOLOGY-ORIENTED CONSERVATION.** Proposals should address research on endangered or threatened species at the state, national or international levels, or address research on critical herpetological habitats. Proposals may be received from individuals only.

2) **GRADUATE STUDENT HERPETOLOGICAL RESEARCH.** Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.

3) **REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS.** Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individuals. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.

4) **HERPETOLOGICAL RESEARCH IN ZOOS.** Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.

Each proposal should include the following information: A) **Background & Objectives** of the proposed project, in terms of its relevance to herpetology, B) **Methods** of carrying out the research or conducting the project, C) **Budget** for the project, according to the guidelines set forth below, and D) **Letter of Support** (if applicable). Proposals should be relatively brief (approx. 5 typed pages).

Budgets for the proposals should not exceed **$250** in each category. The budget request should specifically relate to the project under consideration.

Successful applicants will be expected to submit to SSAR a written report of the results of their research or project, within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to **The Journal of Herpetology** or **Herpetological Review.**

Members of the SSAR Grants-In-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Martin J. Rosenberg (Chairperson), Douglas Fraser (Regional Herpetological Societies), Terry Graham (Conservation), John Groves (Zoo Research) and Linda Maxon (Graduate Student Research).

Individuals submitting proposals should designate to which of the four areas their proposal applies. All proposals must be typewritten and submitted in duplicate no later than **15 APRIL 1981** to:

Martin J. Rosenberg

EARTHWORM *(LUMBRICUS TERRESTRIS)* CONSUMPTION IN CAPTIVE GARTER SNAKES *(THAMNOPHIS SIRTALIS)*

Earthworms are a major food for wild garter snakes, *Thamnophis sirtalis*, (Fitch, 1965) and may be used as food for snakes under laboratory conditions (UFAW, 1967). This study reports the consumption of earthworms *(Lumbricus terrestris)* as the only food for two captive garter snakes over a six year period.

Two garter snakes (1 female, 1 male) were captured in Hunterdon County, New Jersey in 1971. They were housed in a glass and metal frame vivarium (51 x 31 x 28 cm) with a screen top in a room maintained at a temperature of 20 ± 5° C. The floor of the vivarium was covered with gravel, this was removed periodically, the vivarium cleaned and new gravel added. A container of dechlorinated tap water was available at all times. The snakes were fed from approximately April until food refusal occurred (usually October) and were offered earthworms at about 10 day intervals. They were allowed to consume as many earthworms as desired at each feeding.

The results of this study are given in Table 1. The female ate a mean of 5.3 earthworms and the male a mean of 3.8 earthworms at each feeding. During this six year period the female grew 13 cm and the male 9 cm. One litter of 6 was born in 1972.

MUSEUM ACRONYMS* - SECOND EDITION

A preliminary or first edition of a list of museum acronyms was published in **Herpetological Review** in 1978 (vol. 9, no. 1, pp. 5-9). The list was compiled by the members of the Electronic Data Processing Subcommittee of the Joint Herpetological Resources Committee (a committee sponsored by the American Society of Ichthyologists and Herpetologists, Herpetologists' League, and the Society for the Study of Amphibians and Reptiles). The criteria for assigning acronyms for each of the cited collections were given in the introductory statement, and those criteria were followed in preparing this second edition. When the first list was published, users were asked to send their comments, corrections, emendations, and suggestions for additions and deletions to the chairman of the subcommittee. Many did so, and their responses have been individually and critically reviewed. Where there have been conflicts among the recommendations of two or more respondents, choices had to be made, and in these cases the committee accepts full responsibility for having so chosen.

In the first edition of the acronym list, a number of private collections were cited. Private collections have been omitted from the second edition. In the opinion of the committee, although a few private collections are frequently cited in the literature, those of importance are ultimately deposited in recognized institutional collections, and the committee did not want to otherwise encourage the proliferation of non-institutional collections by those seeking to have a private acronym designation. Also, in the first edition several institutions were listed whose collections had previously been transferred to other administrative agencies (i. e. other institutions) for permanent care. These institutions have been culled from the present list inasmuch as the committee members did not feel that the present list need accommodate an historical review of all acronyms, past and present, that have appeared in the literature.

The second edition of the acronym list should be treated as the penultimate step in the construction of a set of alpha-codes for the citation of museum specimens both in the literature and in electronic data processing. Again, users are encouraged to send suggestions for revisions to a member of the Joint Herpetological Resource Committee (see below) for review. This acronym list will be enlarged to include ichthyological collections not co-located at institutions having herpetological collections as well. Thus, a third edition may be expected incorporating minimal changes to the present list, save for obvious errors and additions and/or deletions to the list of herpetological collections.

Clearly this list is not binding on the users. However, hopefully its adoption will result in the standardization of coded collection names, reducing the proliferation of multiple acronyms for given collections, a not uncommon occurrence in past and recent literature.

The committee members thank those who took time to review the first edition of the acronym list and who sent their comments to the committee. Further, to the members of the earlier subcommittee who have not participated in the present update, Drs. William Duellman, C. J. McCoy, and Tom Fritts, the members of the present committee wish to express their appreciation for having done the pioneer work, which made the compilation of the second edition an order of magnitude easier. Dr. Michele Aldrich helped proofread the final version of this list; finding numerous glitches which had escaped the notice of the compilers, her attention contributed to a marked improvement in the published copy.

Should users wish to comment on this list, please address your remarks to the chairman, or to any committee member if otherwise convenient.

For the Joint Herpetological Resource Committee:
Alan E. Leviton, Chairman (CAS)
Roy McDiarmid (USNM)
Scott Moody (OUVC)
Max Nickerson (MPM)
Jose Rosado (MCZ)
Otto Sokol (USA)
Harold Voris (FMNH)

* Two respondents criticised the use of the term "acronym" for the alpha-code names for the collections. The term "eponym" was suggested by one of the two. While neither seems entirely suitable, "eponym" does appear more applicable in this case. However, the word "acronym" is retained in the title of the second edition pending a more thorough etymological review of the options available.

SECTION III
INSTITUTIONAL LIST

(001) University of Alabama, Museum of Natural History [ALA]
University, Alabama, United States 35486

(002) Australian Museum, Department of Herpetology [AM]
6-8 College Street, Sydney, NSW, Australia

(003) Albany Museum [AMG]
Grahamstown, Cape Province, South Africa

(004) American Museum of Natural History, Department of Herpetology [AMNH]
79th Street and Central Park West, New York, New York, United States 10024

(005) Academy of Natural Sciences, Department of Herpetology [ANSP]
19th and Benjamin Franklin Parkway, Philadelphia, Pennsylvania, United States 19103

(006) Australian National University, Department of Zoology [ANU]
Canberra, ACT, Australia

(007) Austin Peay State University, Museum [APSU]
College Street, Clarksville, Tennessee, United States 37040

(008) University of Arkansas, Museum [ARK]
Fayetteville, Arkansas, United States 72701

(009) Academy of Science of St. Louis [ASSL]
St. Louis, Missouri, United States 63100

(010) Arizona State University [ASU]
Tempe, Arizona, United States 85281

(011) Auburn University, Museum [AUM]
Auburn, Alabama, United States 36830

(012) British Museum (Natural History), Department of Zoology [BM]
Cromwell Road, London SW7 5BD, England

(013) Bergen Museum [BMBN]
Bergen, Norway

(014) Bombay Natural History Museum [BNHM]
Bombay, India

(015) Bombay Natural History Society [BNHS]
Bombay, India

(016) Bernice P. Bishop Museum, Department of Zoology [BPBM]
1355 Kalihi Street, Honolulu, Hawaii, United States 96818

(017) Brigham Young University, Monte L. Bean Life Science Museum [BYU]
Provo, Utah, United States 84601

(018) Chicago Academy of Sciences [CA]
2001 N. Clark Street, Chicago, Illinois, United States 60614

(019) California Academy of Sciences, Department of Herpetology [CAS, CAS-SU]
Golden Gate Park, San Francisco, California, United States 94118
Remarks: Includes Stanford University collections separately catalogued (CAS-SU)

(020) Central College [CCB]
Bangalore, India

(021) Instituto Nacional de Microbiologia [CHINM]
Buenos Aires, Argentina

(022) Charleston Museum [CHM]
121 Rutledge Avenue, Charleston, South Carolina, United States 29401

(023) Carnegie Museum, Department of Herpetology [CM]
4400 Forbes Avenue, Pittsburgh, Pennsylvania, United States 15213

(024) Colombo Museum [COM]
Colombo, Sri Lanka

(025) University of Puget Sound [CPS]
1500 N. Warner Street, Tacoma, Washington, United States 98416

(026) University of Southern California, Allan Hancock Foundation [CRE]
Los Angeles, California, United States 90007

(027) Colorado State Teachers College [CSTC]
Greeley, Colorado, United States 80631

(028) Cornell University [CU]
Ithaca, New York, United States 14853

(029) Chulalongkorn University [CUB]
Bangkok, Thailand

(030) Centro de Zoologia [CZL]
Lisbon, Portugal

(031) Central Washington State College, Department of Biology [CWS]
Ellensburg, Washington, United States 98926

(032) Museum fuer Tierkunde [MTKD]
Dresden, Germany (DDR)

(033) Durban Museum [DMD]
Durban, Natal, South Africa

(034) Dallas Museum of Natural History [DMNH]
P.O. Box 26193, Fair Park Station, Dallas, Texas, United States 75226

(035) Fitzsimons' Snake Park [DSP]
Durban, Natal, South Africa

(036) Universidad de Uruguay, Departmento de Zoologia Vertebrados [DZVU]
Montevideo, Uruguay

(037) Estacion Biologia de Rancho Grande, Museo [EBRG]
Maracay, Venezuela

(038) Escuela Nacional Ciencias, Coleccion Herpetozoarios [ECNB]
Mexico City, DF, Mexico

(039) Universidade Federal Rural, Eugenio Izecksohn [EI]
Rio de Janeiro, Brasil

(040) Escuela Politécnica Nacional [EPN]
Quito, Ecuador

(041) Field Museum of Natural History, Division of Amphibians and Reptiles [FMNH]
Roosevelt Road and Lake Shore Drive, Chicago, Illinois, United States 60605

(042) Australian National Wildlife Collection [ANWC]
Canberra, ACT, Australia

(043) Central Australian Museum [CAM]
Alice Springs, NT, Australia

(044) University of Florida, Florida State Museum [FSM]
Museum Road, Gainesville, Florida, United States 32611

(045) Fort Worth Museum of Science and History [FWM]
1501 Montgomery Street, Fort Worth, Texas, United States 76107

(046) Gorgas Memorial Laboratory [GML]
Panama City, Panama

(047) Universitaet Goettingen, Zoologisches Museum [ZFMK]
Goettingen, Germany
Remarks: Merged with Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn (see Record # 183)

(048) Zoologisches Museum fuer Hamburg [ZMH]
Hamburg, Germany

(049) Hebrew University, Department of Zoology [HUJ]
Jerusalem, Israel

(050) Instituto Butantan [IB]
São Paulo, São Paulo, Brasil

(051) Universidad Nacional de Cuyo, Instituto de Biologia Animal [IBMUNC]
Mendoza, Argentina

(052) Universidad Nacional de Bogota, Instituto de Ciencias Naturales [ICNB]
Bogota, Columbia

(053) Instituto Fondamental d'Afrique Noire [IFAN]
Dakar, Senegal

(054) Indian Museum [IM]
Calcutta, India

(055) Instituto Fundacion Miguel Lillo [FML]
Miguel Lillo 205, Tucuman 4000, Argentina

(056) Illinois Natural History Survey [INHS]
Urbana, Illinois, United States 61801

(057) Instituto Oswaldo Cruz [IOC]
Rio de Janeiro, Brasil

(058) Instituto Politécnico Nacional [IPN]
Mexico City, DF, Mexico

(059) Academia de Ciencias, Instituto de Zoologia [IZAC]
Havana, Cuba

(060) Universidad Austral, Instituto de Zoologia [IZUA]
Valvidia, Chile

(061) Universidad de Concepcion, Instituto de Zoologia [IZUC]
Concepcion, Chile

(062) Universita di Cagliari, Instituto de Zoologia [IZUCS]
Cagliari, Sardinia, Italy

(063) James Ford Bell Museum of Natural History [JFBM]
Minneapolis, Minnesota, United States 55400

(064) Krakow Museum [KM]
Krakow, Poland

(065) Kaffarian Museum [KMK]
King William's Town, Cape Province, South Africa

(066) Kruger National Park [KNP]
Skukuza, Transvaal, South Africa

(067) University of Kansas, Museum of Natural History [KU]
Lawrence, Kansas, United States 66045

(068) Los Angeles County Museum of Natural History, Section of Herpetology [LACM]
900 Exposition Boulevard, Los Angeles, California, United States 90007

(069) Musée La-Chaux-de-Fond [LCFM]
La-Chaux-de-Fond, Switzerland

(070) Universidad de Buenos Aires [LIHUBA]
Buenos Aires, Argentina

(071) Landsmuseum Brun [LMB]
Brun, Czechoslovakia

(072) Alvaro de Castro [LMM]
Lourencos Marques, Mozambique

(073) Louisiana State University, Museum of Life Science [LSUS]
8515 Youree Drive, Shreveport, Louisiana, United States 71115

(074) Louisiana State University, Museum of Zoology [LSUMZ]
University Station, Baton Rouge, Louisiana, United States 70803

(075) Awash National Park, Museum [MA]
Awash National Park, Ethiopia

(076) Museo Argentino de Ciencias Naturales, Seccion Herpetologia [MACN]
Avenida Angel Gallardo 470, Buenos Aires, Argentina

(077) Madras Museum [MAD]
Madras, India

(078) Universidade Lisboa, Museu Bocage [MBL]
Faculdade de Ciencias, Lisbon, Portugal

(079) Universidad Central, Museo de Biologia [MBUCV]
Caracas, Venezuela

(080) Museo y Biblioteca de la Zoologia [MBZH]
Havana, Cuba

(081) Museo de Ciencias Naturales [MCNC]
Caracas, Venezuela

(082) Harvard University, Museum of Comparative Zoology [MCZ]
Cambridge, Massachusetts, United States 02138

(083) Museu do Dundo [MD]
Dundo, Angola

(084) Universidad Guanajuato, Museo Alfredo Duges [MDUG]
Guanajuanto, Mexico

(085) Museo Felipe Poey [MFP]
Havana, Cuba

(086) Museu "Gross Antipa" [MGAB]
Bucharest, Romania

(087) Museum d'Histoire Naturelle [MHNB]
Bale, Switzerland

(088) Museum d'Histoire Naturelle [MHNG]
Route de Malagnou, Case Postale 284, Geneve (6), CH-1211, Switzerland

(089) Universidad Nacional Mayor de San Marcos, Museo Historia Natural "Javier Prado" [MHNJP]
Avenida Arenales 1256, Lima, Peru

(090) Museu do Historia Naturale [MHNL]
Lisbon, Portugal

(091) Museo de Historia Natural La Salle [MHNLS]
Caracas, Venezuela

(092) Museo de Historia Natural de Montevideo, Enc. Herpetologia [MHNM]
Montevideo, Uruguay

(093) Museo de Historia Natural de Valpariso [MHNV]
Valpariso, Chile

(094) Prirodosloveni Muzej Slovenije [ML]
Presernova 20, Ljubljana, Yugoslavia

(095) Museo de La Plata [MLP]
Paseo del Bosque, La Plata, Argentina

(096) Museo del Instituto de La Salle [MLS]
Bogota, Colombia

(097) Martin Luther Universitaet [MLU]
Halle-Wittenberg, Germany

(098) Universitaet Magdeburg [MM]
Magdeburg, Germany (DDR)

(099) McGregor Museum [MMK]
Kimberley, Cape Province, South Africa

(100) Muze-ye Melli-ye Tarikh-e Tabii [MMTT]
Tehran, Iran

(101) University of Sydney, Macleay Museum [MMUS]
Sydney, NSW, Australia

(102) Universidade do Rio de Janeiro, Museu Nacional [MN]
Quinta da Boa Vista, Rio de Janeiro, Brasil

(103) Museo Nacional de Ciencias Naturales [MNCN]
Madrid, Spain

(104) Museo Nacional [MNCR]
San Jose, Costa Rica

(105) Musei Nationalis Hungarici [MNH]
Budapest, Hungary

(106) Museo Nacional de Historia Natural, Seccion Herpetologia [MNHNS]
Santiago, Chile

(107) Museo Nacional de Historia Natural [MNHNM]
Mexico City, DF, Mexico

(108) Museo Nacional de Historia Natural [MNHNSD]
Santo Domingo, Republica Dominicana

(109) Museum National d'Histoire Naturelle, Laboratoire des Amphibiens et Reptiles [MNHNP]
8, Rue de Buffon, Paris 75005, France

(110) Museu Paraenese "Emiliano Goeldi" [MPEG]
Belem, Para, Brasil

(111) Milwaukee Public Museum, Vertebrate Zoology [MPM]
800 W. Wells Street, Milwaukee, Wisconsin, United States 53233

(112) Museu do Rio Grande do Sul [MRGS]
Porte Alegre, Rio Grande do Sul, Brasil

(113) Institut Royal des Sciences Naturelles de Belgique [MRHN]
Bruxelles (B-1040), Belgium

(114) Museum Sophia [MSB]
Sophia, Bulgaria

(115) Museo Civico di Storia Naturale di Genova "Giacomo Doria" [MSNG]
Genova, Italy

(116) Museo Civico di Storia Naturale di Milano [MSNM]
Milano, Italy

(117) Museo Civico di Storia Naturale di Torino [MSNT]
Torino, Italy

(118) Madras Snake Park [MSP]
Madras, India

(119) Michigan State University, University Museum [MSUM]
West Circle Drive, East Lansing, Michigan, United States 48824

(120) Memphis State University, Museum of Zoology [MSUMZ]
Memphis, Tennessee, United States 38152

(121) University of Missouri [UMKC]
5100 Rockhill Road, Kansas City, Missouri, United States 64110

(122) University of California at Berkeley, Museum of Vertebrate Zoology [MVZ]
Berkeley, California, United States 94720

(123) Museum Zoologicum Bogoriense [MZB]
Kebun Raya Bogor, Bogor, Java, Indonesia

(124) Museo di Zoologia del Giardino Zoologico [MZGZ]
Rome, Italy

(125) Museo de Zoologia [MZTG]
Tuxtla Gutierrez, Chiapas, Mexico

(126) Universita di Firenze, Museo Zoologico [MZUF]
Via Romana 17, Firenze 50125, Italy

(127) Université de Strasbourg, Musée de Zoologie [MZUS]
Strasbourg, France

(128) Universidade do São Paulo, Museu Paulista [MZUSP]
Avenida Nazareth 481, C. P. 7172, São Paulo, São Paulo, Brasil

(129) Zoological Museum [MZV]
Varsovite, USSR

(130) Naturhistorisches Museum [NHM]
Bern, Switzerland

(131) Naturhistorisches Museum [NHMB]
Basel, Switzerland

(132) Naturhistoriska Museet [NHMG]
Göteborg, Sweden

(133) Naturhistorisches Museum [NHMW]
Ringstrasse, Vienna, Austria

(134) Naturhistoriske Riksmuseum [NHRM]
S-104 05 Stockholm, Sweden

(135) National Museum [NMBO]
P.O. Box 266, Bloemfontein, Orange Free State, South Africa

(136) National Museums of Canada [NMC]
Ottawa, Ontario, Canada

(137) National Museum [NMK]
Nairobi, Kenya

(138) National Museum of Victoria [NMM]
285-321 Russell Street, Melbourne, Victoria 3000, Australia

(139) North Manchurian Museum [NMMH]
Harbin, Manchuria, China

(140) Natal Museum [NMP]
Pietermaritzburg, Natal, South Africa

(141) National Museum [NMS]
Singapore, Singapore

(142) New Mexico State University [NMSU]
University Park, New Mexico, United States 88003

(143) New Orleans Academy of Science [NOAS]
New Orleans, Louisiana, United States 70100

(144) National Museum of Zambia [NMZ]
Livingstone, Zambia

(145) Northern Territory Museum [NTM]
Darwin, NT, Australia

(146) New York State Museum [NYSM]
Cultural Education Center, Empire State Plaza, Albany, New York, United States 12224

(147) Osaka Museum of Natural History [OMNH]
Osaka (y Shibota), Japan

(148) Ohio State University, Museum [OSM]
1659 N. High Street, Columbus, Ohio, United States 43210

(149) Oklahoma State University, Museum of Natural and Cultural History [OSUS]
Stillwater, Oklahoma, United States 74074

(150) Oregon State University, Museum of Natural History [OSUC]
Corvallis, Oregon, United States 97331

(151) Oxford University, Museum [OUM]
Oxford, England

(152) Ohio University, Vertebrate Collection [OUVC]
Athens, Ohio, United States 45701

(153) Ohio Wesleyan University [OWU]
Delaware, Ohio, United States 43015

(154) Peabody Academy of Science [PASSM]
Salem, Massachusetts, United States 01970

(155) Port Elizabeth Museum, Herpetology [PEM]
P.O. Box 13147, Humewood 6013, Port Elizabeth, South Africa

(156) Peking Natural History Museum [PMAM]
Peking, China

(157) Peking University [PUC]
Peking, China

(158) Provincial Museum [PMV]
Victoria, British Columbia V8V 1X4, Canada

(159) Princeton University [PU]
Princeton, New Jersey, United States 08540

(160) Universita di Pisa [PUM]
Pisa, Italy

(161) Queensland Museum [QM]
Gregory Terrace, Brisbane, Queensland, Australia

(162) Queen Victoria Museum [QVM]
Launceston, Tasmania, Australia

(163) Queen Victoria Memorial Museum [QVMS]
Salisbury, Zimbabwe

(164) Musée Royal de l'Afrique Centrale [RGMC]
Tervuren B-1980, Belgium

(165) Raffles Museum [RM]
Singapore, Singapore

(166) National Museum [RMB]
Bulawayo, Zimbabwe

(167) Rijksmuseum van Natuurlijke Historie [RMNH]
Leiden, Holland

(168) Royal Ontario Museum, Ichthyology and Herpetology [ROM]
100 Queen's Park, Toronto, Ontario, Canada

(169) Royal Scottish Museum [RSM]
Chambers Street, Edinburgh, Scotland

(170) South African Museum [SAM]
P.O. Box 61, Cape Town, Cape Province, South Africa

(171) South Australian Museum [SAMA]
North Terrace, Adelaide, South Australia, Australia

(172) Sociedad de Ciencias Naturales La Salle [SCN]
Caracas, Venezuela

(173) San Diego Natural History Museum, Department of Herpetology [SDNHM]
Balboa Park, San Diego, California, United States 92112

(174) Southwest Institute of Biology [SIBAC]
Chengtu, Szechwan, China

(175) Baylor University, Strecker Museum [SM]
Waco, Texas, United States 76703

(176) Natur-Museum Senckenberg [SMF]
Senckenberg Anlage 25, Frankfurt-am-Main, Germany

(177) State Museum [SMG]
Tbilisi, GSSR, USSR

(178) Sarawak Museum [SMK]
Kuching, Sarawak, Malaysia

(179) Southern Illinois University, University Museum [SIUC]
Carbondale, Illinois, United States 62901

(180) Saskatchewan Museum of Natural History [SMNH]
Saskatoon, Saskatchewan, Canada

(181) Staatliches Museum fuer Naturkunde [SMNS]
Arsenalplatz 3, Stuttgart, Germany

(182) Mongolian Academy of Sciences, Biological Institute [BIUB]
Ulan-Bator, Mongolia

(183) Zoologisches Forschunginstitut und Museum Alexander Koenig, Herpetologische Abteilung [ZFMK]
Adenaurallee 150-164, Bonn-1 5300, Germany
Remarks: See remarks under Universitaet Goettingen (Record # 047)

(184) Surinaams Museum [SMP]
Paramaribo, Surinam

(185) State of North Carolina Biological Station [SNCBSH]
Highlands, North Carolina, United States 28741

(186) State Museum [SMW]
Windhoek, Southwest Africa, South Africa

(187) Serengetti Research Institute [SRI]
Seronera, Tanzania

(188) Sul Ross State University [SRSU]
Alpine, Texas, United States 79830

(189) Sacramento State University, Museum of Natural History [SSC]
6000 J Street, Sacramaneto, California, United States 95819

(190) Santo Tomas University, Museum [STUM]
Manila, Luzon, Philippines

(191) Universitaet Bonn, Sammlung der Universitaet [SUB]
Bonn, Germany

(192) Stellenbosch University, J. R. Ellerman Zoological Museum [SUM]
Cape Town, Cape Province, South Africa

(193) Academia Sinica, Southwest Institute of Biology [SWIBASC]
Chengtu, Szechwan, China

(194) Texas A&I University, John E. Conner Museum [TAIC]
Kingsville, Texas, United States 78363

(195) Tel Aviv University [TAU]
Tel Aviv, Israel

(196) Texas A&M University, Texas Cooperative Wildlife Collection [TCWC]
College Station, Texas, United States 77843

(197) Tokyo Imperial University, Science College Museum [TIU]
Tokyo, Japan

(198) Transvaal Museum [TM]
P.O. Box 413, Pretoria, Transvaal, South Africa

(199) Toledo Museum of Health and Natural History [TMS]
Toledo, Ohio, United States 43609

(200) Texas Memorial Museum, Texas Natural History Collection [TNHC]
24th and Trinity, Austin, Texas, United States 78705

(201) University of Texas, Natural History Museum [TNHM]
Austin, Texas, United States 78712

(202) Teylers Strichtina Museum [TSMHN]
Haarlem, Holland

(203) Texas Tech University, Museum [TTU]
P.O. Box 4499, Lubbock, Texas, United States 79409

(204) Tulane University [TU]
6823 St. Charles Avenue, New Orleans, Louisiana, United States 70118

(205) Tokyo Zoological Museum [TZM]
Tokyo, Japan

(206) University of Arizona, Department of Ecology and Evolutionary Biology [UAZ]
Tucson, Arizona, United States 85721

(207) Universidad de Los Andes [UAB]
Bogota, Colombia

(208) Université de Abidjan [UAIC]
Abidjan, Cote d'Ivorie

Regional Society News

SSAR DIRECTORY OF REGIONAL HERPETOLOGICAL SOCIETIES

For the past several years the SSAR has published an annual list of Regional Herpetological Societies. The list that follows is the result of the Regional Herpetological Societies Liaison Committee's activities for the past year. Readers are asked to check the list for accuracy. Societies listed with no address, have had first class letters sent to that address returned. Any wrong addresses, disbanned societies, or missing societies should be brought to the attention of the Committee's chairman, John C. Murphy.

In 1981 the Committee is attempting to collect addresses and data on foreign organizations. If you are in contact with any foreign herpetological societies their addresses would be appreciated. Please send information to: John C. Murphy, 201 Peerless Dr., Plainfield, IL 60544.

BRITISH HERPETOLOGICAL SOCIETY

The British Herpetological Society (BHS), apparently the oldest herpetological society in Europe (founded 1947), aims "to promote the study and protection of amphibians and reptiles, particularly of the European species." The Society is based with the Zoological Society of London. Membership includes both professional and amateur herpetologists and at present totals about 700 members and a further 200 subscribers to the Society's journal, the *British Journal of Herpetology*. Issues of the journal, together with the *BHS Bulletin*, are distributed twice yearly. Eight meetings, held at the Linnaean Society of London, Piccadilly, are organised yearly with supplemental meetings for specialised interests. The BHS "Conservation Committee" (founded 1969) carries out conservation measures for Britain's threatened species in liaison with the UK Government's Nature Conservancy Council. Past work has been funded by the World Wildlife Fund (British National Appeal). The BHS "Captive Breeding Committee" (founded 1976) is coordinating information from Society members on the successful breeding and rearing of species in captivity as a conservation tool, and distributes free leaflets for individual groups and species of amphibians and reptiles. Society members have assisted in providing data for an atlas of species' distribution in the British Isles (1973) and now for the production of a European distribution atlas. An interest is also taken in work by herpetologists in Commonwealth and other English speaking Countries.

Society officers:
President: Dr. J. F. D. Frazer
Joint Secretary: Dr. M. R. K. Lambert
Joint Secretary (administration):
Mr. P. A. W. Bennett
(Treasurer: Mr. D. G. D. Lucas)
Editor, *Br. J. Herpet.*: Dr. M. Peaker
Librarian/Joint Editor, *BHS Bulletin*:
Mr. J. Pickett
Chairman, Conservation Committee:
Dr. T. J. C. Beebee
Chairman, Captive Breeding Committee/
Joint Editor, *BHS Bulletin*:
Mr. S. Townson
Education Officer: Mr. V. F. Taylor

Communications are usually in English, but papers in French, German or Spanish may be accepted by the Editors of the journal and bulletin. Foreign members are most welcome. For information and applications for membership (£5.00 at present), write to: The Secretary, British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY, U.K.

HERPETOLOGICAL STUDY OPPORTUNITIES AT OHIO UNIVERSITY (ATHENS)

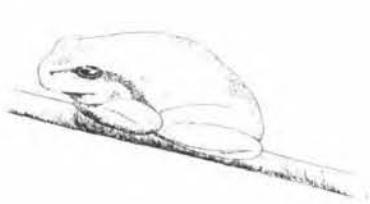
The zoological faculty and graduate program at Ohio University have been relatively small until recently. Over the past three years the faculty has doubled in number because of a teaching association with the new College of Osteopathic Medicine. Because most of the new faculty are young and pursuing active research programs, the graduate student program should grow in national reputation. Excellent opportunities for the study of reptiles and amphibians are also available in the form of two faculty members, new research facilities, a collection of reptiles and amphibians and many natural environmental areas.

Henri Seibert is the senior herpetologist and Professor of Zoology. He teaches courses in Herpetology, Ornithology and Field Ecology. He has built a large teaching and research collection of reptiles and amphibians from Ohio and the Appalachian Regions. His knowledge of the distribution and natural history of local species is tremendous. Currently he is receiving research support from the Ohio Division of Wildlife and is conducting population studies on several salamander species.

Scott Moody is the junior herpetologist and has joined the faculty this year as Assistant Professor of Biomedical Science. He just completed his doctoral dissertation entitled "Phylogenetic and historical biogeographical relationships of the genera in the family Agamidae (Reptilia: Lacertilia)" at the University of Michigan in Ann Arbor. His research and teaching interests are: lizard phylogenetics and biogeography, narrow hybrid zone phenomena, karyology of lizards, behavior and reproductive isolating mechanisms of lizards and frogs, comparative anatomy of the skeleton, muscles of the pectoral girdle and nerve pathways of the limbs of lizards, comparative histology of epidermal glandular structures of lizards and lizard fossils of the Mesozoic.

A temperature-controlled animal research facility is available on campus. Moody will have available in his laboratory a Wild dissecting scope with camera lucida and Nikon camera mount, a compound binocular microscope for histology and karyology, soft X-ray machine, reel-to-reel tape recorder, slow motion movie camera and analyzer and a video computer terminal. In other laboratories, transmission and scanning electron microscopes and sonagram machines for analyzing animal sounds are available. The University has an IBM/370 digital computer.

Non-herpetological faculty who could directly benefit students of herpetology include Gerald Svendsen who studies the sociobiology and evolutionary ecology of mammals and Joseph Eastman who studies the evolution, ecology, anatomy and physiology of Antarctic fishes.



Students interested in all aspects of the biology of reptiles and amphibians are encouraged to apply to the M.S. and Ph.D. programs.

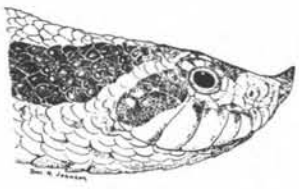
POSITIONS

BIRD/HERP PREPARATOR

Carnegie Museum of Natural History has a vacancy for a **Scientific Preparator** for the Section of Birds and the Section of Amphibians and Reptiles. Starting salary will be $12,792., plus benefits. Candidates should have a B.S. in vertebrate biology, or equivalent work experience. A thorough knowledge of preparation techniques for scientific specimens of birds (study skins, fluid preserved, skeletons) and amphibians and reptiles (fluid preserved, skeletons), and the ability to record and transcribe data accurately and legibly are essential. Job experience in a scientific collection is **required.** In addition to preparation duties, the position will involve assisting with the management of the collections (installation and arrangement of specimens, packing and unpacking shipments, fumigation, etc.), and opportunities to participate in field work. Experience in field collecting of birds, amphibians and reptiles is desirable, but not required. **This is not a research position.** Send curriculum vitae and the names and telephone numbers of two references to Dr. C. J. McCoy, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Ave., Pittsburgh, PA 15213. The position will be filled after 1 January 1981. Carnegie Institute is an Equal Opportunity Employer.



Legislative Alert

The following amphibians and reptiles are currently (*i.e.*, as of 1 **October** 1980) listed under the Endangered Species Act of 1973 (as amended) and/or the CITES Treaty. Persons involved in "activities" with these species are required to possess the appropriate permits/certificates.

BOOK REVIEWS

International Zoo Yearbook - Volume 19. P. J. S. Olney, Ed. 450 pp. Published 1979 The Zoological Society of London. $34.00 Hardbound; $27.00 Softcover.

What's covered with baby *Crocodylus* and adult *Thelotornis* and is something everyone working with a living herp collection should have? Wrong—it's not a Pierre Cardin motorcycle seat.

Volume 19 of the International Zoo Yearbook presents, as usual, an excellent collection of papers covering a broad spectrum of exotic animal husbandry. The price, while rather steep in absolute terms, is not unreasonable compared to $75.00 volumes in other series. The 126 pages of herpetological material cover everything from exhibition techniques to anaesthetics, though the bulk of the section deals with breeding of various species.

A note on "Improving the calcium content of mealworms" (p. 254), while not included in the reptile section, should not be overlooked (the technique would probably work with many insects used as food). Similarly, Huff's note on facilities of the Reptile Breeding Foundation (p. 267) is interesting.

The non-herpetological papers contain a wealth of information for those herpetologists interested in general animal behavior or reproductive biology.

Red Book of USSR - Rare and endangered specimens of animals and plants.
Editor: A. Boradin Editorial Board: Ziljarov, Sokolov, Tahtadjan, Cicin, Brejnev Borodin Ministry of Agriculture of USSR. Moscow, 1978.
This book is not commercially available, but is in USSR scientific libraries and institutes. (Government Organization) The list of amphibians and reptiles includes illustrations, information about range, reproductive biology, and abundance of the following species:

AMPHIBIA
- Caudata
  - *Ranodon sibiricus* - rare, endemic
  - *Onychodactylus fisheri* - rare, poorly known
  - *Mertensiella caucasica* - rare endemic
  - *Triturus montandori* - becoming rarer
  - *Triturus vittatus ophryticus* - rare endemic, poorly known
- Anura
  - *Pelobates syriacus* - endemic, small range
  - *Pelodytes caucasicus* - rare, poorly known
  - *Bufo calamita* - rare, becoming rarer

REPTILIA
- Testudines
  - *Trionyx sinensis* - becoming rarer through human activity, slow reproduction
  - *Testudo graeca* - becoming rarer through overcollecting, slow reproduction
- Aquamata (Sauria)
  - *Zymnodactylus kotsehiyi damilewski* - rare, small range
  - *Alzophylax spinicauda* - rare, poorly known
  - *Eublepharis turemenicus* - rare, small range, poorly known
  - *Agama ruderata* - rare, small range
  - *Phrynocephalus maculatus* - small range (isolated population), rare
  - *Phrynocephalus rossikowi* - reproduction small, poorly known, sporadically located populations, small range
  - *Varanus griseus caspius* - reduced in number through intensive collecting and killing
  - *Eumeces latisculatus* - rare, small range
  - *Ablepharus kitaibelii chernowi* - small range, small number
- Squamata (Serpentes)
  - *Ptyas mucosus* - reduction of numbers as result of intensive collecting
  - *Elaphe situla* - small range, reduction of number as result of collecting and killing, probably will be extirpated in USSR
  - *Elaphe longissima* - patchy distribution, rare, killed by man
  - *Oligodon taeniolatus* - very rare, small range
  - *Rhynchocalamus melanocephalus saturini* - small range, rare, poorly known
  - *Naja naja oxiana* - rare, reduction of number by intensive collecting and killing
  - *Vipera kaznakowi* - small range, poorly known
  - *Vipera ammodytes transcaucasiana* - sporadic local populations, small range and abundance
  - *Vipera (xanthina) raddei* - decrease of numbers, small range, relatively small populations

The decrease in number of a species is caused by collecting, by destruction of biotopes and unknown reasons. Red Book Specimens are protected by local law and limited in collecting for sale, exhibit, etc.

BOOK REVIEW

McKeown, S. 1978. **Hawaiian Reptiles and Amphibians.** Oriental Publishing Co. 80pp. ill. Obtainable from ISBS, PO Box 555, Forest Grove, OR 97116. $3.50.

Of the 4 Amphibia and 18 reptiles presently occurring in Hawaii or its surrounding waters, only the sea snake and the three marine turtles can be considered indigenous. Seven species of lizards were probably present in Hawaii before the arrival of Captain Cook, possibly transported unintentionally by the early Polynesians. The remainder of the herpetofauna is the result of man's recent activities, including escapees from pet shops and purposeful introductions. Thus, 148 adult *Bufo marinus* were introduced onto Oahu in 1932 and two years later their number had swelled to over 100,000! Other introductions apparently failed.

For each species there are brief notes on life history, identification and distribution and each species is illustrated by one or more photographs which are outstanding in their clarity and color rendition. These superb pictures alone are worth obtaining the booklet even if you never visit Hawaii.

TECHNIQUES

AN IMPROVED DESIGN FOR A THREAD TRAILING DEVICE USED TO STUDY TERRESTRIAL MOVEMENTS OF TURTLES

Thread trailing devices designed to study the terrestrial movements of turtles have been used by several workers (see Dolbeer, 1971; Reagan, 1974; and Schwartz and Schwartz, 1974; among others). Although varying in detail, all of these involve a source of friction created by a spool of thread mounted on a horizontal shaft or axle. The device described below eliminates this source of friction by eliminating the need for an axle. It was conceived and successfully utilized after difficulty was encountered with an axle-type device being used to study the terrestrial movements of individuals of *Kinosternon subrubrum* (Scott, 1976).

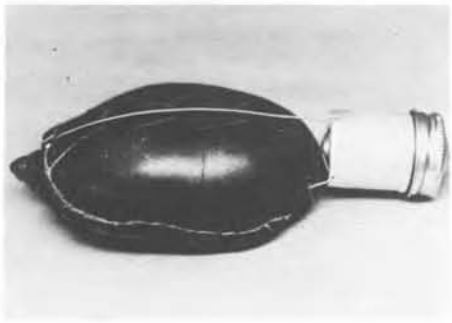

Fig. 1. Trailing device attached to carapace of adult male *Kinosternon subrubrum*.

This new device consists of a light-weight spool of fine thread mounted lengthwise inside an empty 35 mm aluminum film canister, which can be fastened to the posterior portion of the turtle's carapace using three small wires (Fig. 1). The canister contains a thread-release mechanism similar to those employed in commercial spincast fishing reels, which are noted for their low-friction casting quality. The device is sketched in detail in Fig. 2.

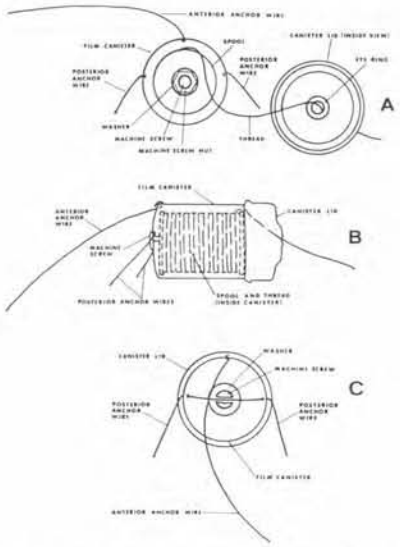

Fig. 2. Diagram of trailing device showing details of construction. A. Posterior view of canister with lid removed. B. Lateral view showing position of spool inside. C. Anterior view.

Commercially available polyester thread wound on a 114 m (125 yards) capacity styrofoam spool is recommended for use in the device. Round-headed steel machine screws (1.5 inches X 8/32) and the matching washers and hexagonal machine screw nuts can be used to anchor the spool to the inside of the canister. An eye ring should be installed on the inside of the lid of the canister to afford a smooth opening through which the thread can trail.

UNDERWATER TRAPS FOR AQUATIC TURTLES

The chicken wire trap described by Iverson (1979) has decided advantages (primarily cost and cleanliness) over the hoop net described by Legler (1960) but appears to be somewhat more difficult to transport. Both utilize tapered throats at either end of the trap and are effective for the collection of aquatic turtles. This paper discusses variations in design of hoop nets for turtles and compares them to chicken wire traps.

Throats. All commercial turtle nets I have seen are single throated. The other end may have a draw-string release for easy access to the turtles. Nets made with a throat at either end (Fig. 1) may be set parallel with the shore line to increase accessibility to feeding turtles. They have the disadvantage of providing two openings through which turtles may escape. A length of seine twine threaded through the throat acts as a purse string to control the size of the opening. Legler (*op. cit.*) found a ten inch long by three inch high ovoid to be adequate. The shape of the opening is flexible permitting turtles with shells deeper than three inches to enter the trap. Indeed, I have removed snapping turtles from traps having throats seemingly too small to admit them. Two lines attached to the purse string and edge meshes of the throat on opposite sides hold the throat in position and keep the opening in the form of a pointed-ended oval. The other ends of these lines are attached to either the wall of the trap or to the interior hoop or hoops. In a four-hoop trap, attachment is to the second hoop from the opposite end. The lines should be as nearly horizontal as possible when the traps are set. Making one of the purse strings with a non-sliding loop on either end and attaching the lines to this throat with "clothespin" snaps (sold for sport or commercial fishing) allows one end to be opened easily to facilitate removal of large turtles. One of the snaps holds the two loops of the purse string and two meshes at the edge of the throat; the other is attached to the mesh only. After removal of a turtle, the purse string must be re-threaded through the meshes at the edge of the throat but the time expended on this chore is far less than that expended on trying to remove a 35-pound snapping turtle from a trap without opening the throat. Number 4 or 5 snaps are easy to work with.

Hoops. Round hoops are standard and easier to form. Oval hoops, although harder to form, have compensating advantages. Traps built around oval hoops show less tendency to roll and can be set in shallower water.

Three or four hoops are usually used. With four hoops, the lines holding the throats may be attached to the hoops for strength. Three-hoop traps are lighter and provide a center attachment for the line running from the trap to the shore or other attachment. With this arrangement, the traps can even be suspended in deep water.

Hoops may be made of wood, fibreglass, aluminum, or galvanized steel. Wood is bulky and does not last well. Fibreglass hoops are expensive and must be tied to the trap walls, rather than threaded through the mesh. Legler *(op. cit.)* recommended quarter-inch aluminum tubing. Aluminum rod of the same diameter can also be used. Aluminum hoops are light in weight and easily bent into the desired shape. They have the disadvantage of being easily damaged. Galvanized steel is heavier and somewhat harder to form (buying it in a coil helps) but is almost indestructible when properly galvanized. The ends of the metal hoops are joined by couplings or sleeves of tubing and crimped with pliers or with a hammer and metal punch. Advantages and disadvantages of the two metals are as mentioned above. Copper tubing seems to share the disadvantages of each. The choice of material depends upon the trapping conditions. If the traps can be carried by car to the trapping site, the durability of galvanized steel is desirable. If the trappers must carry the traps any considerable distance to the water, the light weight of aluminum becomes more important.

Mesh. In 1960, Legler recommended cotton webs. Since then cotton has almost entirely given way to nylon. Nylon will neither rot nor pick up much water but it benefits from treatment with a product such at "Netcoat" which is supposed to improve strength and abrasion resistance. Creosoted or tarred nets have the disadvantage of leaving the hands black and hard to clean.

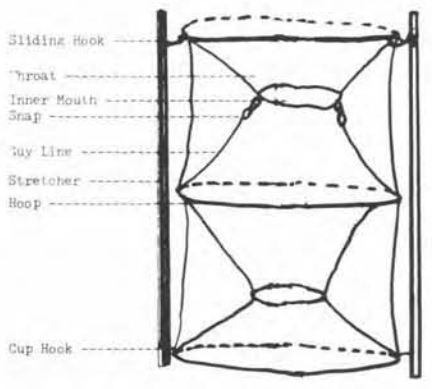

Figure 1. Double throated hoop net, seen from above, showing use of snaps on one pair of guy lines for quick release of large turtles.

Mesh size will usually be three-quarters of an inch square measure (an inch and a half stretched measure) unless hatchlings must be taken. Then half inch square mesh becomes necessary despite the added weight, expense, and difficulty of repair.

Stretchers. Some form of tension member is required to keep the hoop net extended. Stakes are bulky (four are required) and may hold poorly in soft mud. Laths with L-hooks in either end have been tested and shown to have drawbacks. Slightly undersized traps can be stretched with laths because the latter will bow out. Oversized traps can sometimes be stretched by adding a third lath to the usual two but the traps often sag anyway. Legler *(op. cit.)* described a non-adjustable stretcher of half inch dowel with a screw hook in either end. He also described an adjustable one with a screw hook soldered to a copper sleeve which slides along the dowel, forming a friction sleeve. A screw hook at one end of the dowel and a screw at the other keep the friction sleeve from falling off. Legler later changed to L-hooks soldered to metal washers for his sliding friction sleeves. A more easily manufactured friction sleeve consists of a brass closed S-hook, just large enough so that one loop can slide freely over the dowel. The other loop is opened into an "L" shape with pliers and rotated 90 degrees. A similar device can be bent from wire of roughly the same diameter as that in a wire coat hanger, *e. g.* single strand aluminum guy wire (Fig. 2). The stretcher is assembled in the usual manner with a brass cup hook or screw hook at one end, the friction sleeve in the middle, and a brass screw at the other end. Drilling pilot holes for the screws helps to avoid splitting the dowel. Legler *(op. cit.)* suggested painting, varnishing, or lacquering the dowels to prevent their soaking up water and warping. I have had good results soaking them in linseed oil to waterproof them.

As dowels are readily available only in three foot lengths, this places an upward limit on the length of the hoop net. Garden shops, however, may have dahlia stakes, which are longer and are also suitable for trap manufacture.

Size of Trap. Legler *(op. cit.)* found hoop nets 19 inches in diameter (five feet in circumference), 33 inches long, and with 12 inch throats to be the most useful in general collecting. This length has the advantages of permitting the use of standard dowels as stretchers and is also short enough to permit the operator to reach in and change the bait easily. The dimensions can be modified for specialized collecting.

Bait Holders. One of the cheapest and most readily available bait holders, described by Legler *(op. cit.)*, consists of a square of quarter inch mesh hardware cloth folded around the bait and suspended in the center of the trap just above the throats. These and ones made of window screening are sharp edged and can quickly shred the fingers. Plastic vials, two inches in diameter and three and a half inches high make adequate if short-lived bait holders. The cap is suspended from the middle of the trap by a short cord and may be weighted by a three-eighths ounce lead sinker. The vial itself, perforated by 20 or so quarter inch holes, can be filled with bait and quickly snapped on the lid. The life span of these bait holders is about one or two months of daily use. If bait is abundant, you can use the commercial snapper trappers' technique of simply throwing half a large carp into the trap unless there are reasons (Iverson, *op. cit.*) for not allowing the turtles to feed on the bait.

Tie Lines. Where the trap is set by throwing it from shore, or must be anchored, a leash of 12 to 15 feet of heavy nylon seine twine (about 0.2 inch diameter) can be attached to the middle hoop. Attaching it with a large clothespin snap (as found on some fish stringers) allows quick removal of the leash when not needed.

Materials. One style of hoop net may be made with:

A) Three-quarter inch square nylon netting, four by four and a half feet. This makes a net 32 inches long with 11 inch throats. Circumference is four feet. To make a larger or smaller diameter net, vary the four foot width of the mesh and the circumference of the hoops.
B) Twelve feet of hoop material, quarter inch diameter.
C) Three couplings for hoops.
D) Two half inch dowels.
E) Two brass S-hooks large enough to slide along the dowels or about 10 inches of heavy aluminum wire.
F) Two small brass round-head screws.
G) Two brass screw hooks or cup hooks.
H) Two number 4 or 5 clothespin snaps.
I) 12 to 15 feet of 0.2 inch diameter nylon seine twine.
J) Nylon seine twine to match that used in the mesh.
K) Bait holders.
L) Materials to treat dowels and mesh.
M) Large clothespin snap (optional).

Comparison of Traps. Materials for the Iverson chicken wire trap are half as costly as those for a hoop net (galvanized steel hoops, one inch square nylon mesh). In addition, they may be assembled in a quarter of the time (half an hour vs. two hours). Their non-absorbency allows them to be transported from the trap site cleaner and less smelly than hoop nets. Single-unit construction limits losses of parts.

Determination of relative durability and trapping efficiency of the two styles of trap could best be made by people who have fished both styles in the same habitats. Durability, at least, may vary with habitat. For example, brackish water accelerates both rusting and galvanic action.

Hoop nets appear to be far the easier to transport. Weight of the two traps is roughly equal (about three pounds) when galvanized steel rod is used. Use of aluminum tubing cuts the weight of the hoop net to between one third and one half of that of the chicken wire trap. The difference in volume of the collapsed traps is more striking, the hoop nets occupying one fifth of the space of a chicken wire trap. In addition, hoop nets collapse by themselves when the stiffeners are removed and need not be compressed.

Hoop nets appear to have advantages over

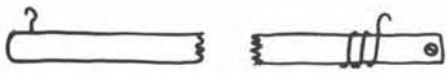

Figure 2. Stretcher for hoop net. It consists of a half inch dowel, screw hook, sliding wire hook, and round head screw (as stopper).

chicken wire traps for trapping very small turtles in that smaller mesh is available for the webbing. If large turtles are present, whether wanted or not, the hoop nets appear far superior. Whereas large snapping turtles have everted the funnels of chicken wire traps to escape, the lines holding the throats of hoop nets keep the turtles securely within the nets. Attaching these lines to one of the throats with snaps (clothespin hooks) allows the turtle's quick removal from the trap. Muskrats, on the other hand, usually gnaw their way through the mesh and repairs to the web of a hoop net take a minute or two.

When cost of materials and speed of assembly are important and the traps can be driven up to the site, the chicken wire traps are the better. When traps must be transported by boat or packed in to the site, the hoop net becomes desirable.

ACKNOWLEDGEMENTS

I am indebted for some of the above net modifications to James L. Christiansen and John M. Legler. Some fo the modifications were developed and tested while working for LGL Environmental Research Associates in southeastern Iowa. During the course of the study, we trapped every kind of turtle reported from the area, exclusive of *Macroclemmys*, the alligator snapping turtle, which is rare if present at all.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Dept. of Herpetology, Houston Zoological Gardens, Houston, Texas 77001.

CAPTIVE PROPAGATION OF ENDANGERED HOUSTON TOADS

Two years ago the Houston Zoo received a $2,170 grant from the U.S. Fish and Wildlife Service for a captive propagation/release program of the endangered Houston toad *(Bufo houstonensis)*.... To help increase the wild population, the Houston Zoo proposed to raise the toads from eggs to adults in a laboratory situation.... The laboratory-raised adult toads could then be released to enhance the breeding potential of the wild population.

The Zoo was highly successful in raising tadpoles, with mortality rates of only 9% in 1978 and 5% in 1979. Problems were encountered in raising the toads, however, so several experimental groups were established to determine the best possible conditions for the toad's survival. It was found that toads raised in naturally planted outdoor enclosures grew faster and demonstrated a significantly lower death rate than those raised indoors.

This year the Zoo was awarded a two-year grant of $21,878.52 to continue its research on the Houston toad. The grant financed the development of an outdoor off-exhibit propagation area at the Zoo. The area contains greenhouses with removable roofs and sides. The roofs and sides are placed on the enclosures only during inclement winter weather. Personnel and assorted equipment are also supplied through grant funds.

Controlled experiments are being conducted to determine why the toads survive better outside than those housed inside....

The University of Texas permitted the use of several one-acre outdoor toad enclosures in which to raise Houston toads. Marked toads will be released at designated sites when they reach the age of one year. Those released will be from both the Zoo and the University of Texas. By comparing the survival of released toads from both sources, the most successful release program can be designed.

CAPTIVE REPRODUCTION OF *VIPERA RUSSELLI* (SHAW, 1797).

Bibliographical data about the reproduction of *Vipera russelli* refer mainly to observations carried out in captivity. They are generally fragmentary and incomplete (Bannerman, 1907; Flynn, 1932; Sochurek, 1949; Robinson and Woodward, 1955; Meyer-Holzapfel, 1969).

The conditions under which vipers are kept in our breeding colony have already been described in detail (Naulleau, 1973 b). Briefly, vipers are kept in laboratory in large terraria, 3.80 m long, 2.25 m wide and 1.05 m high, along with cages 0.50 m or 1 m long, 0.50 wide and 0.50 high. Weather conditions are about the same all the year. A thermal gradient between 18 and 50° C from 8 a.m. to 8 p.m. enables the vipers to choose their optimum temperature. Photoperiod is from 8 a.m. to 8 p.m. During the night, the temperature is kept to at least 18° C with permanent heating.

The vipers are mainly fed with micromammalia, especially rats *(Rattus norvegicus)*, and mice *(Mus musculus)*, and also chicks *(Gallus gallus domesticus)*.

The biology of Russell's viper bred under those conditions has been published (Naulleau and van den Brule, 1979). The first litters observed in the laboratory were obtained from pregnant females imported from Pakistan. We are now dealing with the 2nd captive bred generation.

A. Sexual maturity

With *Vipera russelli*, as with all ophidia, sexual maturity is late. If we take into account the period included between the earliest mating and parturition, the birth of young vipers from a viper born and bred in laboratory occured at the age of 23 months.

B. Sexual behaviour and mating

This species does not show a particular behaviour as compared with other vipers. Pairing by means of "dances" between male and female, and fights between males, do not occur.

In sexual behaviour, the male explores the female's body with quick strokes of the tongue as he is moving on it or along it with jolting movements, while the female is extremely passive. Then, the male twines its tail round the female's so that both cloacae join for mating. Only one hemipenis takes part in mating, which generally lasts a long time.

C. Parturition

The following information is from snakes raised in our colony. In Fig. 1 and 2, we have showed the weight and size growth of N° 7 male, who mated with 3 different females and of N° 2 female who was the first to give birth to young vipers in laboratory. Important biological events (shedding, mating, litters) have also been mentioned in these figures together with the monthly food intake. Notice that three of the observed matings took place at the beginning of the year (in January and February) (Table 1 and Fig. 1). Three matings were carried out between brother and sister.

In Fig. 3, we have mentioned the months when parturitions cited in the literature occurred, along with the dates of the litters obtained in the laboratory from pregnant females from Pakistan, and 3 laboratory born females. Parturitions take place from April to September with a conspicuous maximum in July, and this with vipers that were kept in captivity in very different regions and under undoubtedly dissimilar conditions, not mention in the literature. Moreover, Wall (1921), quoted by Saint-Girons (1972) reports that in Ceylon and peninsular India, parturition generally takes place in June or July. On the other hand, in Indonesia, births take place from January to March (van Hoesel, 1958). According to Robinson and Woodward (1955), the birth of 23 young vipers lasted more than 30 hours. We were able to observe one litter only, with N° 13 female; all other births took place in our absence. Parturition of 11 young vipers and 8 infertile eggs took place 4 h 25 mn and proceeded as follows (from 9 h 45 a.m.): 1° young viper: 2° infertile egg; 3° young viper; 4°: 2 infertile eggs; 5°: 2 young vipers; 11 h 05 a.m.: 6° young viper; 7° infertile egg; 11 h 56: 8°: 2 infertile eggs; 12 h 05: 9° infertile egg; 10° young viper; 12 h 25: 11° young viper; 12 h 40; 12° young viper; 1 h 05 p.m.: 13° young viper; 1 h 40 p.m.: 14° young viper; 2 h 10 p.m.: 15° infertile egg and 16° young viper.

Russell's viper is a prolific snake since it can produce from 20 to 63 young vipers measuring from 212 to 275 mm (Angel, 1950). In Ceylon and in Peninsular India, the number of young vipers for each litter varies from 9 to 63 (Wall, 1921, quoted by Saint-Girons, 1972). In captivity, we have recorded litters of 8 to 22 young vipers with an average of 15.4, and from 0 to 9 infertile eggs, with an average of 5.4 (Table 2). There is an average of 8 females for 5.9 males in a litter, which gives a sex-ratio of 1.3 in favour of the females.

The length of the young vipers born in the laboratory fits more or less with the literature data which give 235 mm and 290 mm as extreme values (Flynn, 1932; Robinson and Woodward, 1955; Meyer-Holzapfel, 1969) (Table 3), our minimum (165 mm) and maximum (320 mm) being nevertheless a little different. The sizes and weights of young vipers

at their birth are perceptibly the same between males and females (Table 3).

Discussion and Conclusion.

The maximum number of 22 young vipers we obtained in captivity is weak with *Vipera russelli*, generally more prolofic (sometimes up to 63 young vipers) (Angel, 1950; Wall, 1921 quoted by Saint-Girons, 1972; Schmidt and Inger, 1960) but large vipers, such as *Bitis*, almost reach that number (59 with *Bitis gabonica*) or largely exceed it (80 with *Bitis arietans*), (Pitman, 1974). The average number of young vipers per litter seems related to the size of the species, but small vipers may well have large litters, as with *Vipera aspis* where the maximum recorded number of young vipers is 22 (Naulleau, 1975). These numbers of young vipers at birth are impressive, but death-rate is high, due to predators and above all, lack of food, as the young cannot easily find prey to suit their size. Moreover, sexual maturity for these vipers is late and reached after many years, which means that in spite of the number of vipers at birth, very few of them will reach reproductive age, and among certain species, females do not breed every year. As for *Vipera russelli*, we do not know the age of sexual maturity and the reproductive cycle in nature, but sexual maturity is very likely to occur later than when in captivity (2 years for both sexes). In the same way, the period between mating and breeding which lasts 125 days in laboratory, must be longer in natural conditions, as we have showed with *Vipera aspis*, (Naulleau, 1970, 1971, 1973 a and b). Sexual maturity is indeed more closely connected to growth than to age, and thus directly related to the conditions of captivity chosen to be as favourable as possible. The period between mating and breeding also has a lot to do with these conditions.

RESUME

La maturité sexuelle chez *Vipera russellii* est atteinte à l'âge de 2 ans dans les deux sexes. Les comportements sexuels sont comparables à ceux observés chez d'autres Vipéridés. Un seul des hémipénis participe à l'accouplement qui est de longue durée, jusqu'à 17 heures au moins. Les mises bas ont lieu préférentiellement en Juillet. La seule que nous ayons pu observer, de 11 vipéreaux et 8 oeufs non fécondés, a duré pendant 4 h 25 mn. Le nombre de vipéreaux par portée est de 15,4 et le nombre d'oeufs non fécondés de 5,4. Le sex-ratio est de 1,3 en faveur des femelles. La taille et le poids des vipéreaux à la naissance sont sensiblement les mêmes dans les deux sexes, respectivement 27,3 cm chez les mâles, 27 cm chez les femelles, 11,8 g chez les mâles et 11,9 chez les femelles.

SUMMARY

Sexual maturity of *Vipera russelli* is reached at the age of 2 yrs. for both sexes. Sexual behaviours can be compared to those of many other vipers. Only one hemipenis takes part in mating, which lasts a long time (up to 17 hours). Litters are more likely to occur in July. The only birth of a litter that we were able to observe lasted 4h 25, with 11 young vipers and 8 infertile eggs. We have recorded an average of 15.4 young vipers in a litter and 5.4 infertile eggs. Sex-ratio is 1.3 in favour of the females. The sizes and weights of newborn vipers are the same for both sexes, that is, 27.3 cm for the males, 27 cm for the females, 11.8 g for the males and 11.9 for the females.

NEWSNOTES

INTERNATIONAL STRATEGY FOR THE CONSERVATION OF EUROPEAN HERPETOFAUNA

With the increasing pressure on all species of European herpetofauna, the time for a concerted and unified European initiative by those most active in the field of herpetological conservation and field research has arrived.

The intention is to present, as soon as possible, a single succinct plan for the conservation of European herpetofauna, which incorporates the ideas, data, information, criticisms and suggestions put forward by active field herpetologists. The plan will then be presented to those European bodies capable of offering substantial funds.

Contributions are welcomed by all individual herpetologists regardless of their nationality or their affiliation to any society. We are not proposing a new society nor do we seek anything other than the rapid completion of a plan of action written and agreed by those individuals most involved with herpetology. In order to expedite this intent we propose that Mr. John Coborn, Cotswold Wild Life Park, Burford, Oxfordshire, England will act as co-ordinator, receiving plans or reports and disseminating these to other herpetologists for comment. ●

FUNDS AVAILABLE

The Forest Service, Caribbean Natural Forest (USDI) has reserved FY '81 funds to support ecological study of the Puerto Rican boa *(Epicrates inornatus)*. Funding will be at least sufficient to support a study of the boa in the National Forest (El Yunque), and may be sufficient to support an island-wide study. The Service hopes to fund a study in the first quarter of 1981, to be completed about a year later. Persons interested in more information, or wishing to submit proposals, should contact:

Mr. Jerry Bauer
P.O. Box K
Luquillo, P. R. 00673 ●

ERRATA

HR 11 (2): William F. Holmstrom's name was misspelled in Contents (Holstrum) and on p. 32 (Holstrom) (**HR** editor, blush here).

HR 11 (3): P. 80, *Pseudemys s. elegans* note; J. Harry Reynolds, Jr. — not Renolds. ●

SOCIETAS EUROPAEA HERPETOLOGICA

The SEH was founded by 24 herpetologists from eight European countries in fall, 1979. The aims of this new scientific society are to further scientific research, to participate in all problems regarding the conservation of amphibians and reptiles, and to encourage closer collaboration between all European and non-European herpetologists.

President: Josef Eiselt, Vienna, Austria; Vice-President: Jean Lescure, Paris, France; General Secretary: Marinus S. Hoogmoed, Leiden, Netherlands; Vice-Secretary: Alfredo Salvador, Leon, Spain; Treasurer: Heinz Wermuth, Ludwigsburg, West Germany; Vice-Treasurer: Franz Tiedemann, Vienna, Austria; First Co-Editor: Helmut Hemmer, Mainz, West Germany; Second Co-Editor: Alain Dubois, Paris, France.

The society's journal, **AMPHIBIA-REPTILIA,** will be devoted to scientific papers on all aspects of herpetology. This journal will now provide a medium of communication for herpetologists in Europe and elsewhere who previously had only the nationally organized and terrarium oriented journals and the three American based journals. Articles will be published in English, French, German or Spanish. Each issue will contain original papers, shorter articles, book reviews and news of the SEH. One volume will include four issues with approximately 90 pages each with a page size of 17 x 24 cm. Reproduction of illustrations will be of high quality.

Manuscripts will be reviewed by an editorial board comprised of 10 European herpetologists. Manuscripts may be submitted to either of the two co-editors:

Prof. Dr. Helmut Hemmer
Zoologisches Institut
Gutenberg Universitaet
Postfach 3980
D-6500 Mainz
West Germany

Dr. Alain Dubois
Laboratoire Reptiles/Amphibiens
Museum national d'Histoire Naturelle
25, Rue Cuvier
F-75005 Paris
France

Membership is open and worldwide to all interested persons and institutions. Active membership dues will be DM 70.00 (approximately $40.00) per year, which will include a subscription to the journal.

Send your name, address, nationality and membership dues to either Treasurer:

Dr. Franz Tiedemann
Naturhistorisches Museum
Postfach 417
A-1014 Wien
Austria

Dr. Heinz Wermuth
Staatliches Museum fuer Naturkunde
Arsenalplatz 3
D-7140 Ludwigsburg
West Germany

Library subscriptions will cost DM 108.00 and may be ordered from:

Akademische Verlagsgesellschaft
Postfach 1107
D-6200 Wiesbaden
West Germany ●

HANDBUCH DER REPTILIEN UND AMPHIBIEN EUROPAS

The style of the Handbuch der Reptilien und Amphibien Europas is similar to the Catalogue of American Amphibians and Reptiles but the accounts are longer and more detailed. Each account will include a diagnosis and comparison, illustrations, systematic consideration, geographic distribution and map, ecology, development, behavior and literature bibliography.

The Handbuch will be published in five volumes:

1. Echsen I (Geckos, Agamen, Chamaeleons, Schleichen, Skinke und Eidechsen = Lacerten I)
2. Echsen II (Eidechsen II = Lacerten)
3. Schlangen und Schildkroeten
4. Schwanzlurche
5. Froschlurche

If ordered prior to publication, the first volume will cost DM 168.00. Following publication the price will be DM 216.00.

Information may be obtained from:
Akademische Verlagsgesellschaft
Postfach 1107
D-6200 Wiesbaden
West Germany

Subscriptions may be obtained from:
Buchhandlung
Ziegan oHG
Potsdamer Strasse 180/182
1000 Berlin 30
West Germany ●

HERP INVENTORY AVAILABLE

The "Inventory of Live Reptiles and Amphibians in North American Collections, Current January 1, 1980" is now available.

This inventory gives information on location and sex of all individual reptiles and amphibians of 912 species and 1,093 forms, held in 49 public and 33 private collections. There are also thirty-two pages of miscellaneous breeding information, including dates of egg laying and hatching, types of incubation media used, incubation temperatures, etc., as reported by the responding collectors. The complete report is 1-XVI + 156 pages.

The 1980 inventory is limited in numbers and will not be reprinted. Copies are now

available for $15.00 each, including packaging and postage, from:

Frank L. Slavens
P.O. Box 30744
Seattle, Washington 98103

Zoos and other institutions can be billed; all others please send money order or check with order.

HERPETOLOGICAL ART EXHIBIT

A herpetological art exhibit will be held during the 1981 joint annual SSAR/HL meeting at Memphis State University (9-14 August). If you wish to display, contact James S. Jacob, Local Committee Chairman, Ecological Research Center, Department of Biology, Memphis State University, Memphis, TN 38152. Telephone: (901) 454-2588 or 2581.

Necturus lewisi INFO NEEDED

The North Carolina State Museum of Natural History is conducting a life history and distribution study of *Necturus lewisi*. Funds for this study are provided by a cooperative agreement between the Office of Endangered Species, U. S. Fish and Wildlife Service, and the N. C. Wildlife Resources Commission, and by the N. C. Department of Agriculture. The primary purpose of the study is to acquire data sufficient to enable USFWS to assess the salamander's status with respect to the national list of endangered and threatened native fauna.

Any records of *N. lewisi*, supported by voucher specimens, could be helpful in establishing the salamander's present or past distribution. Contributions will be duly acknowledged in a future publication.

Please send information to Alvin L. Braswell, N. C. State Museum of Natural History, Box 27647, Raleigh, NC 27611. ●

HR NEEDS DRAWINGS

The supply of small line drawings **HR** uses for column breaks is depleted. Rather than keep showing you all the same ones over and over, I'd be grateful if artistically talented readers would contribute new stock. We cannot pay for material, but this is a good opportunity to place your work in a widely distributed publication. Please indicate if originals are to be returned. Format is unrestricted. Please do not send Xerox copies as they don't reproduce too well. Thanks!

GRP

ANOTHER *HERPERVERT. REV.*

If you would like to be immoralized, oops—immortalized, in yet another of these important satirical publications, contribute **now.** Cartoons, prose, poetry, phenograms, whatever are all welcome. Use of pseudonyms is suggested to subvert retribution. Please do not send **ideas** for the editor to expand upon. Said editor has enough ideas of his own and grows weary ghost writing. Photos whose content may be humorously twisted by caption or judicious surgery are especially welcome. The editor has never considered himself immune from parody, for those who've wondered. Appropriate themes for Tennessee are evolution, Appalachian snake handlers, etc.

ENDANGERED SPECIES PERMIT INFO.

SSAR members may avail themselves of the extensive permit information services of the Association of Systematics Collections at reduced cost (SSAR is a member society of ASC). Services cover state, federal and (to a certain extent) international permits and regulations. For more information, contact:

Thomas J. Berger
ASC
Museum of Natural History
University of Kansas
Lawrence, KS 66045
(913) 864-4867 ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10(1):1.

CAUDATA

AMBYSTOMA ANNULATUM (Ringed Salamander). USA: ARKANSAS. Baxter Co: .1 km W Midway. 29 September 1979. Johnny Hewett. Verified by S. E. Trauth. Auburn University Museum (AUM 29369). Boone Co: 12.8 km S Harrison. 1 April 1970. S. E. Trauth. (AUM 29370). These two new county records fill a distributional gap in the Ozark Plateau of Arkansas between Sharp County (McDaniel, V. R. 1975, SSAR Herp. Review 6:115) and Madison County (Anderson, J. D. 1965. Cat. Amer. Amph. Rept. 19.1).

Submitted by **STANLEY E. TRAUTH,** Department of Biology, Georgia Southwestern College, Americus, Georgia 31709. ●

AMBYSTOMA ANNULATUM (Ringed Salamander). USA: MISSOURI: Lincoln Co: Cuivre River State Park, 5 km E Troy. 18 September 1978. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (45-172). Record for county and northern range extension of at least 15 km from previous records in St. Charles and Warren counties (Johnson, 1977, The Amphibians of Missouri, Univ. of Kansas, Lawrence, 134 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R. R. #1, Box 25, Troy, Missouri 63379. ●

AMBYSTOMA MACULATUM (Spotted Salamander). USA: MISSOURI: Lincoln Co: Cuivre River State Park, 5 km E Troy. 19 March 1979. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (79-22). Record for county and northern range extension of at least 15 km from previous records in St. Charles and Warren counties (Johnson, 1977, The Amphibians of Missouri, Univ. of Kansas, Lawrence, 134 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R. R. #1, Box 25, Troy, Missouri 63379. ●

AMBYSTOMA OPACUM (Marbled Salamander). USA: MISSOURI: Lincoln Co: Cuivre River State Park, 5 km E Troy. 17 September 1978. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (45-167). First record in state from north of the Missouri River and a northern range extension of at least 40 km from previous records in St. Louis and Franklin counties (Johnson, 1977, The Amphibians of Missouri, Univ. of Kansas, Lawrence, 134 pp.)

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R.R. #1, Box 25, Troy, Missouri 63379. ●

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: MISSOURI: Lincoln Co:

Cuivre River State Park, 5 km E Troy. 31 March 1979. Bruce Schuette. Verified by Tom R. Johnson and Ron Goellner. Officially listed as a RARE species in Missouri, this specimen was photographed and released (photograph deposited with the Natural History Section of the Mo. Dept. of Conservation). First record in state from north of the Missouri River and a northern range extension of at least 90 km from previous records in Crawford and St. Genevieve counties. The whole previous Missouri population was itself a disjunct population from their main range (Johnson, 1977, The Amphibians of Missouri, Univ. of Kansas, Lawrence, 134 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R.R. #1, Box 25, Troy, Missouri 63379. ●

ANURA

RANA AREOLATA AREOLATA (Southern Crawfish Frog). USA: TEXAS: Kaufman Co: 3.2 km S of Prairieville. 6 September 1980. R. A. Baker. Dallas Museum of Natural History (DMNH 5103). Prairieville. 31 May 1980. R. A. Baker (DMNH 5104). Identified by W. Seifert. These specimens close the gap between the Red River and the Trinity River populations (Conant, 1975. A Field Guide to the Amphibians and Reptiles of Eastern and Central North America. Houghton Mifflin Co., Boston).

Submitted by **WAYNE SEIFERT,** Division of Lower Vertebrates, Dallas Museum of Natural History, P.O. Box 26193, Dallas, Texas 75226. ●

TESTUDINES

CHRYSEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: NEW JERSEY: Mercer Co: Lake Carnegie in Princeton Township and Delaware-Raritan Canal in West Windsor Township adjacent to lake. Observed basking in lake by R. J. Stein and W. K. Eames on 20 April 1976. Four specimens collected from lake in basking traps on 2 June, 21 June, and 13 July 1977 and one hatchling collected from canal by dip netting on 16 June 1977 by R. J. Stein, W. K. Eames, and D. C. Parris. Verified by R. J. Stein. New Jersey State Museum (NJSM-P317, P318, P319, P320, P321). In addition to the five preserved specimens, more than one hundred observations have been made of this species basking in the lake, the canal, and the pond formed at the aqueduct of the Millstone River where it flows into Lake Carnegie. This first record of an established population in New Jersey undoubtedly originated as an introduction, as did numerous other populations (Conant, R. 1975. A Field Guide to the Amphibians and Reptiles of Eastern and Central North America, Houghton Mifflin Co., Boston). It is to be expected that this species will expand its range throughout central New Jersey following the Delaware-Raritan Canal and the Millstone River to the Raritan River drainage.

Submitted by **RAYMOND J. STEIN, WILLIAM K. EAMES, and DAVID C. PARRIS,** Bureau of Science, New Jersey State Museum, 205 W. State Street, Trenton, New Jersey 08625. ●

LACERTILIA

ANOLIS LIMIFRONS. Mexico: Quintana Roo: 0.5 km N Akumal. 1 March 1980. J. Parmerlee and S. Phillips. Direccion de la Fauna Silvestre, Mexico D.F. (field number 48). Coba. 4 March 1980. J. Parmerlee and R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 01326). Verified by W. E. Duellman, University of Kansas Museum of Natural History. Previously only one coastal record from northern Quintana Roo (Lee, J. C., 1980. University of Kansas Museum of Natural History Miscellaneous Publication No. 67). These records indicate a continuous distribution south to the vicinity of Tulum.

Submitted by **R. POWELL and J. PARMERLEE,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

ANOLIS SAGREI (Cuban Brown Anole). USA: FLORIDA: Alachua Co: Gainesville, SW 2nd Ave., 100 m E of 13th St. 15 and 17 August 1980. J. R. Bain and M. L. Wygoda. Florida State Museum (UF 47681-47683). Verified by P. Meylan. Collected on sidewalk near dense hedge. Several hatchlings, juveniles, and adults noted. Apparently an isolated breeding population. Locality is approximately 62 km NE of the Gulf Hammock, Levy County record (Funk, R. 1979. SSAR Herp. Review 10(3):102.) and approximately 102 km WSW of the St. Augustine, St. Johns County record (Meylan, P. 1977. SSAR Herp. Review 8(2):29.). This is the first inland report of *A. sagrei* from northern Florida.

Submitted by **MARK L. WYGODA,** Department of Zoology, University of Florida, Gainesville, Florida 32611 and **JAMES R. BAIN,** Department of Natural Sciences, Florida State Museum, Gainesville, Florida 32611. ●

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink). USA: ARKANSAS: Bradley Co: 18 km W of Monticello on AR 4, T13S, R9W, Sec. 1. 18 March 1979. J. D. Walls. Verified by V. R. McDaniel. Arkansas State University Herpetol. Mus. (ASUHM 3922). First record for the county and narrows the gap between central Arkansas and extreme southcentral Arkansas populations (Dellinger, S. C., and J. D. Black. 1938. Occ. Pap. U. Arkansas Mus. (1):1-47; Dowling, H. G. 1957. Occ. Pap. U. Ark. Mus. 3:1-51; Conant, R. 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **CHRIS T. MCALLISTER,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

SCELOPORUS UNDULATUS ELONGATUS (Northern Plateau Lizard). USA: WYOMING: Carbon Co: 1.6 km S, 4.0 km E Overland Crossing, North Platte River, T18N R85W SW¼ Sec. 1, 2042 m. 1 August 1980. G. Hammerson and B. Lapin. Identified by G. Hammerson, verified by H. M. Smith. Univ. Colorado Mus., Boulder, UCM 52679-52692. First record outside Colorado River drainage area; collection site is east of the Continental Divide. *Sceloporus u. erythrocheilus* inhabits the N. Platte R. drainage area in the Laramie Mountains to the east and northeast (Maslin, 1956, Herpetologica 12:292). The status of *S. undulatus* in the apparent hiatus between *S. u. elongatus* and *S. u. erythrocheilus* in southern Wyoming needs clarification.

Submitted by **GEOFFREY A. HAMMERSON,** Department of Environmental, Population & Organismic Biology, University of Colorado, Boulder, Colorado 80309, and **BETH P. LAPIN,** Colorado Natural Heritage Inventory, 1726 Champa, Suite 307, Denver, Colorado 80202. ●

SCINCELLA LATERALIS (Ground Skink). USA: MISSOURI: Lincoln Co: Cuivre River State Park, 5 km E Troy. 5 April 1978. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (46-299). First record in state from north of the Missouri River and a northwestern range extension of 53 km from previous record in St. Louis County (Anderson, 1965, The Reptiles of Missouri, Univ. of Missouri Press, Columbia, 330 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R.R. #1, Box 25, Troy, Missouri 63379. ●

SCINCELLA LATERALIS (Ground Skink). USA: MISSOURI: Monroe Co: Mark Twain State Park, 2 km S Florida. 28 June 1978. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (46-302). Record for county and northwestern range extension of 90 km from Lincoln County (135 km from previous record in St. Louis County) (Anderson, 1965, The Reptiles of Missouri, Univ. of Missouri Press, Columbia, 330 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R.R. #1, Box 25, Troy, Missouri 63379. ●

SPHAERODACTYLUS GLAUCUS (Dwarf gecko). Mexico: Quintana Roo: 10 km N Playa del Carmen. 29 February 1980. H. Gregory and R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 01332). Verified by R. Powell. Only previous record from northern Quintana Roo is from Puerto Juarez (Lee, J. C., 1980. University of Kansas Museum of Natural History Miscellaneous Publication No. 67). This record extends

known distribution southward some 50 km and suggests the previously described locality is not an isolated population.

Submitted by **J. PARMERLEE and R. POWELL,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

SERPENTES

CARPHOPHIS AMOENUS VERMIS (Western Worm Snake). USA: ILLINOIS: McDonough Co: About 21 km SW Macomb and 3.2 km NNW Colmar (Sec. 31, T5N, R4W). 17 April 1971. G. R. Thurow. Verified by H. Marx, Field Museum of Natural History. Western Illinois University Collection (WIU 513). This and other specimens seen up to 1977, when this disjunct colony probably became extinct due to xerification associated with increased cattle grazing. One duplicate county specimen collected in 1980 from near Fandon (Sec. 32, T5N, R3W) and released. First record for county, and extends range about 45 km E from earlier western state border records.

Submitted by **G. R. THUROW,** Department of Biological Sciences, Western Illinois University, Macomb, Illinois 61455. ●

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake) USA: TEXAS: Henderson Co: 4 km E of highway junction 274 & 85 on 85. 4 July 1979. R. Moore. Identified by W. Seifert. Dallas Museum of Natural History (DMNH 5105). Extends the range one county westward (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, DMNH Bulletin 2).

Submitted by **WAYNE SEIFERT,** Division of Lower Vertebrates, Dallas Museum of Natural History, P.O. Box 26193, Dallas, Texas 75226. ●

CONOPHIS LINEATUS (Mexican rear-fanged snake). Mexico: Quintana Roo: 14 km N Akumal. 5 March 1980. M. Henderson and R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 01335). Verified by R. Powell. Second known locality from Quintana Roo, extends known distribution southward some 70 km (Lee, J. C., 1980. University of Kansas Museums of Natural History Miscellaneous Publication No. 67).

Submitted by **R. POWELL and J. PARMERLEE,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

CROTALUS DURISSUS (Tropical rattlesnake). Mexico: Quintana Roo: 20 km N Playa del Carmen. R. Powell and J. Parmerlee. Bobby Witcher Memorial Collection, Avila College (BWMC 01336). Verified by R. Powell. First record from northern Quintana Roo (Lee, J. C., 1980. University of Kansas Museum of Natural History Miscellaneous Publication No. 67). Lee (1980) indicates a complementary distribution of *C. durissus* and *Bothrops asper* in the northern part of the Yucatan Peninsula. He suggests competitive exclusion. This record would negate that hypothesis.

Submitted by **R. POWELL and J. PARMERLEE,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

ELAPHE TRIASPIS (Green ratsnake). Mexico: Quintana Roo: 5 km N Akumal. 1 March 1980. H. Gregory and N. Laposha. Bobby Witcher Memorial Collection, Avila College (BWMC 01342). Verified by R. Powell. This is the third known locality from Quintana Roo and the only coastal record (Lee, J. C., 1980. University of Kansas Museum of Natural History Miscellaneous Publication No. 67). Extends known distribution about 80 km SE and NE from previous sites.

Submitted by **J. PARMERLEE and R. POWELL,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

OXYBELIS AENEUS (Mexican vine snake). Mexico: Quintana Roo: 10 km N Playa del Carmen. R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 01345). Verified by R. Powell. This is the first record reported from the east coast of Quintana Roo (Lee, J. C., 1980. University of Kansas Museum of Natural History Miscellaneous Publication No. 67). Extends known distribution approximately 50 km to the east.

Submitted by **R. POWELL and J. PARMERLEE,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

STORERIA O. OCCIPITOMACULATA (Northern Redbelly Snake) USA: INDIANA: Lake Co: Griffith, Hoosier Prairie, 136 meters S. Main St., 0.4 km E of intersection with Kennedy Avenue. 24 June 1979. A. Resetar and D. Roti Roti. Verified by Alan Resetar. Field Museum of Natural History (FMNH 211854). This is the first record, documented by a specimen, of the occurrence of *Storeria o. occipitomaculata* in the northern half of Indiana. This species occurs in adjacent Will and Cook counties in Illinois (Smith, P. W. 1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Survey, Vol. 28, Art. 1) Minton (1972, Amphibians and Reptiles of Indiana, Indiana Acad. of Sci., Monog. No. 3) mentioned a record from Gary, but regarded it as questionable. Griffith is within a few miles of the Gary city limits. This specimen was collected in a tall grass prairie. Subsequent specimens collected in Munster (Lake County, Indiana) were collected in an old field habitat.

Submitted by **ALAN RESETAR,** Division of Amphibians and Reptiles, Field Museum of Natural History, Roosevelt Road at Lake Shore Drive, Chicago, Illinois 60605. ●

VIRGINIA VALERIAE ELEGANS (Western Earth Snake). USA: MISSOURI: Lincoln Co: Cuivre River State Park, 5 km E Troy. 6 April 1978. Bruce Schuette. Verified by Tom R. Johnson. St. Louis Museum of Science and Natural History (46-298). Second record from northern Missouri, but the first from NE part of state. Record for county and range extension of 53 km north from previous record in St. Louis County, 190 km east from Saline County record and 270 km southeast from Grundy County record (Anderson, 1975, The Reptiles of Missouri, Univ. of Missouri Press, Columbia, 330 pp.).

Submitted by **BRUCE SCHUETTE,** Missouri Department of Natural Resources, Cuivre River State Park, R.R. #1, Box 25, Troy, Missouri 63379. ●

DISTRIBUTIONAL RECORDS FOR JOHNSON COUNTY, TEXAS

The recent review of the distribution of amphibians and reptiles in Texas by Raun and Gehlbach (1972), and subsequent reports (cited by Karges, 1978) indicate a paucity of records for Johnson County, Texas. The following new county records and range extensions were collected by the author (unless otherwise noted) and are deposited in the Collection of Vertebrates, The University of Texas at Arlington (UTACV). All identifications were made by the author and verified by Bern W. Tryon and David B. Heckard.

ANURA

BUFO SPECIOSUS (Texas Toad). 7.0 km N Godley on FM rd. 2435. 7 May 1979. G. Carl and S. Myers. A-7120. Extends range margin eastward from Hood Co.

BUFO VALLICEPS (Gulf Coast Toad). 11.0 km W Cleburne on U.S. 67. 6 May 1979. A-7101.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). 15.4 km W Rio Vista on FM rd. 916. 30 April 1979. A-7098.

HYLA CHRYSOSCELIS/VERSICOLOR (Gray Treefrog). 15.4 km W Rio Vista on FM rd. 916. 30 April 1979. A-7097.

PSEUDACRIS CLARKI (Spotted Chorus Frog). 8.8 km W Rio Vista on FM rd. 916. 30 April 1979. A-7099. 1.6 km NW Godley on Texas 171. 1 May 1979. A-7100.

TESTUDINES

CHRYSEMYS CONCINNA TEXANA (Texas River Cooter). 0.2 km N of county rd. 1108 on Mill Ck. 13 May 1979. G. Carl and R. Stevens. R-8737. Partially bridges the gap between Tarrant and McLennan Counties.

TRIONYX SPINIFERUS PALLIDUS (Pallid Spiny Softshell). 0.2 km N U.S. 67 on FM rd. 2331. 13 May 1979. G. Carl and R. Stevens. Private collection of R. Stevens; will be donated to UTACV.

SERPENTES

CROTALUS ATROX (Western Diamondback Rattlesnake). 2.2 km W Ham Creek Park on County rd. 1108. 6 May 1979. R-8700. Bridges the gap along the eastern range margin between Tarrant and Hill Counties.

ELAPHE OBSOLETA LINDHEIMERI (Texas Rat Snake). 12.2 km N Godley on FM rd. 2435. 1 May 1979. R-8698.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). 7.5 km N Godley on FM rd. 2435. 25 April 1979. R-8707. Fills a gap in distribution along the western edge of the range between Tarrant and Bosque Counties.

LAMPROPELTIS GETULUS HOLBROOKI X SPLENDIDA (Speckled X Desert Kingsnake). 2.6 km N Godley on FM rd. 2435. 6 May 1979. G. Carl and S. Myers. R-8702. 3.8 km N Godley on FM rd. 2435. 7 May 1979. R-8706.

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). 10.2 km W Cleburne on U.S. 67. 6 May 1979. R-8705.

NERODIA RHOMBIFERA RHOMBIFERA (Diamondback Water Snake). 16.2 km S Godley on FM rd. 2331. 6 May 1979. R-8704.

OPHEODRYS AESTIVUS (Rough Green Snake). At Mill Ck. 4.6 km W of Ham Creek Park on county rd. 1108. 6 May 1979. R-8701.

PITUOPHIS MELANOLEUCUS SAYI (Bullsnake). 0.8 km S Godley on FM rd. 2331. 6 May 1979. R-8703.

SALVADORA GRAHAMIAE LINEATA (Texas Patchnose Snake). 9.0 km S Cleburne State Park on FM rd. 1434. 6 May 1979. R. 8699. Extends range margin eastward from Somervell Co.

I thank John P. Karges for his assistance.

OCCURRENCE OF *PELAMIS PLATURUS* (LINNAEUS) IN EL SALVADOR

Previous records of *Pelamis platurus* in the Pacific marine waters of Central America included Panama, Costa Rica, Nicaragua and Guatemala (Kropach, 1975) and Honduras (Wilson, McCranie, and Porras, 1978; Cruz, Wilson, and Espinosa, 1979), but no definite locality records were known from El Salvador, although its occurrence had been expected there (Hoge and Romano, 1971).

Four specimens of *Pelamis platurus* are now available from Salvadoran marine waters. The locality records for these are: Playa de San Diego, Departamento de la Libertad, 13° 28'N,89° 14'W (HH 418 ♀, 595 ♀); Playa de San Blas, Departamento de La Libertad, 13° 29' 05"N,89° 23'W (MHNES 30-573 ♂); Playa El Pimental, Departamento La Paz, 13° 23'N, 89° 06'W (MHNES 30-574 ♀). All specimens were found washed up on the beach.

The Salvadoran specimens have the following characteristics: supralabials 8 to 9; infralabials 10 to 13; preoculars 1-1; postoculars 2-2(3), 2-1(1); anterior temporals 2-2(2), 2-3, ?-3; posterior temporals 4-3, 2-2, 3-3, ?-4; ventrals 287 in single male and 316-342 (mean, 329.3) in three females; anal plate divided; total length 234, 250, 560, 605 mm; tail length 31, 59(2), 60 mm. Color in life was as follows: bicolored, black dorsally, yellow ventrolaterally; black coloration on tail forming a sawedged pattern; some black spots ventrolaterally over a yellow background.

The Salvadoran localities are approximately 162 km W from those recorded by Wilson, McCranie and Porras (1978) and Cruz, Wilson and Espinosa (1979) in the Golfo de Fonseca in Honduras.

The distribution of *Pelamis platurus* in the eastern Pacific, as presently known, ranges from the Gulf of California to Ecuador (Kropach, 1975), including El Salvador and Honduras.

ACKNOWLEDGEMENTS

I thank the authorities at the Museo de Historia Natural de El Salvador (MHNES) for allowing me to examine material in their collections and Sres. Guillermo Linares and José A. Chávez for presenting me with a specimen. I also thank Sra. Estela de Gómez for typing the manuscript. HH refers to my private collection in El Salvador.

TO ORDER:

Make check or money order payable to SSAR: ☐ $20 paperbound ☐ $24 clothbound

Prices include packing and shipping world-wide. Address orders to Dr. Henri C. Seibert, Department of Zoology, Ohio University, Athens, Ohio 45701, U.S.A. Receipt sent on request only. Mark here ☐ if you wish to have a complete pricelist of SSAR publications including the *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles,* and the publications of The Ohio Herpetological Society.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted.

NEW COORDINATOR: As of this issue I will no longer be the coordinator of Current Literature. Expanding interests in botany and other demands upon my time have necessitated my relinquishing the responsibilities of coordinator. I have enjoyed working with the Current Literature project. It has been gratifying to me to see the project grow, especially in its world-wide scope. I am confident that the new coordinator, Mr. Joseph Dinardo, is extremely capable as his interest in the herpetological literature is long standing. Searchers should now send citations to

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

SSAR CATALOG OF AMERICAN AMPHIBIANS AND REPTILES

THE CATALOG. Imprinted binder, taxonomic tabs. accounts 1-220

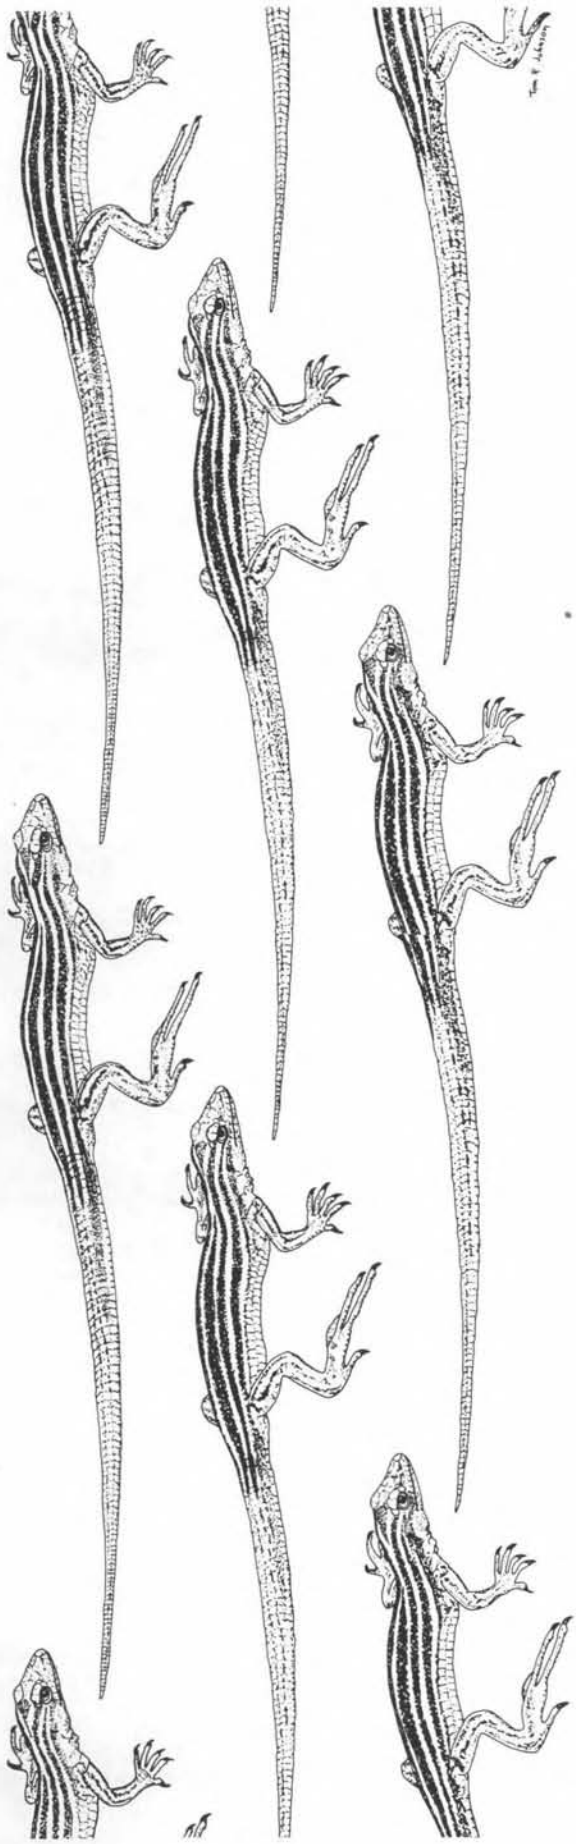
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars**, and several **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$12.00
Regular member	$15.00
Sustaining member	$20.00
Contributing member	$25.00
Institutional	$25.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

PROCEEDINGS OF THE 1980 SSAR GENERAL BUSINESS MEETING IN MILWAUKEE

The annual general business meeting of the SSAR was called to order by President Robert G. Webb at 3:20 PM on 8 August 1980 in the Wisconsin Room East of the Student Union at the University of Wisconsin at Milwaukee.

President Webb made the following announcements: 1) The SSAR Board appointed Herbert Dessauer, LSU Medical Center, to replace Roger Conant on the SSAR Board of Directors for the remainder of Conant's term of office (until 31 December 1981); 2) The new SSAR *Contributions to Herpetology* series has been successfully launched, with initial sales of the first number in this series having recovered nearly two-thirds of the capital outlay; 3) Stephen G. Tilley will become editor-in-chief of the SSAR's *Catalogue of American Amphibians and Reptiles* effective 1 January 1981, and the SSAR will continue, during 1981, to issue 25 accounts of the CAAR without a price increase; 4) Authors of major papers (not notes) published in the *Journal of Herpetology*, if they wish separates, will be required to order and purchase 300 separates; 5) Individuals publishing in the *Journal* are strongly encouraged to deposit voucher specimens in university or museum collections to document their research; 6) The 1982 Silver Anniversary Meeting of the SSAR will probably be held in Raleigh, North Carolina, providing the Annual Meeting Site Committee successfully concludes current negotiations; 7) The winner of the 1980 Kennedy Award of $100 was announced (see *Herp Review*); 8) The recipients of the 1980 SSAR Grants-In-Herpetology were announced (see *Herp Review*); 9) The SSAR has expressed interest in an initial proposal to co-sponsor, with the Cornell University Laboratory of Ornithology, a new edition of the popular record "Voices in the Night," and the SSAR Board will consider such a proposal in detail in the near future; 10) and, The SSAR Board expressed interest in publishing the Crocodilian symposium held at this meeting provided that a mechanism for implementation can be found and provided that reviews indicate that such a book would be a substantial contribution to herpetology.

President Webb called on Joseph Collins, chairperson of the Nominating Committee, to present his committee's slate of nominees for 1981 office, as follows:

For President-elect:	Kraig Adler
	Ronald Brandon
For Secretary:	Joseph T. Collins
For Treasurer:	Henri Seibert
For Board of Directors:	Max A. Nickerson
	Stephan Tilley
	Marvalee Wake
	Richard Wassersug

There being no nominations from the floor, James Knight moved and Joseph Collins seconded to accept the recommendations of the Nominating Committee. The motion passed unanimously.

President Webb pointed out that a critical financial situation existed within the SSAR, and announced that the SSAR Board of Directors had established the following dues and subscription schedule for 1981: Students, $15.00; Sustaining, $25.00; Contributing, $30.00; and Institutional Subscription, $30.00. In addition, President Webb stated that the SSAR Board had instituted a $3.00 inflationary surcharge on regular dues, raising them from $15.00 to $18.00. He asked for and received a unanimous vote of commitment from the assembled SSAR members to institute this surcharge for 1981 only.

SSAR treasurer Henri C. Seibert announced that the SSAR Board had approved a budget of $66,475 for fiscal 1981, and stated that the SSAR membership continued to grow.

President Webb then yielded the floor to the Resolutions Committee composed of Frances J. Irish, Robert A. Thomas, Thomas H. Fritts and Ronn Altig.

1) Frances J. Irish presented the following resolution:

Whereas, the 1980 annual meeting was convened at the University of Wisconsin at Milwaukee and co-hosted by the Milwaukee Public Museum from 6 to 10 August, and;

Whereas, the elegance of the City of Milwaukee has served to attract a gathering of distinguished herpetological scholars, and;

Whereas, the hospitality of all concerned has been quite generous, and;

Whereas, the meetings have been efficiently orchestrated and the accomodations have been superior, and;

Whereas, the assembled membership has benefited greatly from the symposia offered, and enjoyed the opportunity to interact with the many participating foreign scientists, therefore be it

Resolved, that the membership extends its appreciation to the local committee and its assistants, consisting of Max A. Nickerson, Albert A. Williams, Sherman Ketcham, Mary Binder, Robert W. Henderson, Drew Hildebrandt, Dan Janik, John Minnick, Maria Plonczynski, Jeff Riedi, Rich Sajdak, Lee Tischler, Ed Cukjuti, Adrian Czajka, Pat Alexander, Garard Thielke, Vali Kiaie, Liz Tylendra, Alan Ragnlie, Kevin Hanley, Phil Whitford, Gary Beyer, Dave Grambow, Ann Bernier, Margie Mullet, Earl Olfe, Paul Miller, Cynthia Vernon, Roger Opey, Mary Ann Opey, Dave Sorensen, Marje Ketcham, Cliff Van Beek, Fred Prohaska, Joan McDonald, Nathan Kraucunas, Patrice Lastufka, Keith Chipman, Mark Tohalka, Stan Hopkins, and Jessica Johnson, and to the chairpersons of the three SSAR symposia, Bern W. Tryon, John C. Murphy and Rich Seigel, and to the Wisconsin Herpetological Society.

The resolution was adopted unanimously.

2) Robert Thomas (better known as the Urban Cowboy) delivered the following resolution (as a minority report):

Whereas, the 1980 annual meeting was held at the University of Wisconsin at Milwaukee and co-hosted by the Milwaukee Public Museum from 6 to 10 August, and;

Whereas, the beer breweries and parlors of the city of Milwaukee have served to attract a gathering of relatively extinguished herpervertologists (with the exception of three unnamed souls), and;

Whereas, the meeting has been efficiently orchestrated and the accomodations were superior (except for the hot water, cold water, no water, no air-conditioning, and the absence of selected shower curtains), and;

Whereas, John Wright has once again failed to attend a major herpetological meeting, and;

Whereas, Dick Vogt *did* somehow manage to wander into Milwaukee (herding his flock of sheep, as it were), and;

Whereas, Roy McDiarmid lost a Uher tape recorder over a wager concerning 600 or so country-music-loving nuns in Texas, therefore be it

Resolved, that in the future the Resolution Committee *not* be pressed into service on such short notice before the General Business Meeting, and that Jim Jacobs, local chairperson for next year's meeting, be instructed to present to next year's assembled membership a list of honky-tonk (and rock 'n' roll boogie) dance halls.

A few weak yeas carried the above resolution, the silent majority of members having been too stunned to react.

3) Kraig Adler presented the following resolution:

Whereas, Stephen R. Edwards has faithfully served as the SSAR secretary for many years, and;

Whereas, under press of other responsibilities he felt it necessary to resign this position in March 1980, and;

Whereas, the SSAR owes Steve a great debt of gratitude for his service to the SSAR, therefore be it

Resolved, that the SSAR officers, Board of Directors and assembled membership extend to Steve its warmest thanks for his service to the SSAR.

The resolution was adopted unanimously.

4) Joseph T. Collins offered the following resolution:

Whereas, Richard G. Zweifel has diligently served as editor-in-chief of the SSAR Catalogue of American Amphibians and reptiles, and;

Whereas, he has set and maintained the highest of standards and quality in the production of the catalogue, and;

Whereas, after years of service to the SSAR, Richard has resigned as editor-in-chief effective the end of 1980, and;

Whereas, he will continue to serve herpetology as section editor for the Anura, therefore be it

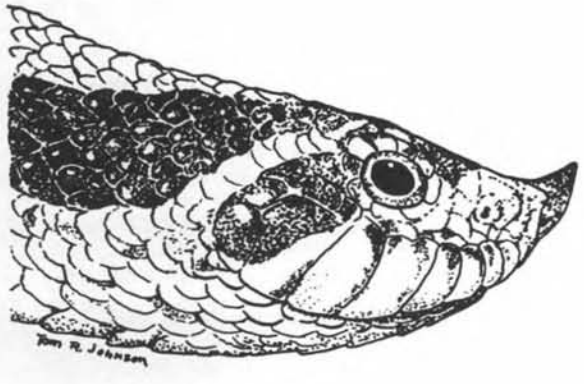
Resolved, that the SSAR and its members extend to Richard Zweifel its heartfelt thanks and gratitude for a job done with excellence and high quality.

The resolution was adopted unanimously.

President Webb then introduced Jim Jacobs, local committee chairperson for the 1981 meeting at Memphis. Jim presented a slide show and talk extolling the virtues of Memphis, and promised the assembled SSAR membership that a list of good dance halls would be ready upon our arrival next August.

The SSAR General Business meeting adjourned at 4:50 PM.

Respectfully submitted,



JOSEPH T. COLLINS
SSAR Secretary ●

1980 RECIPIENTS OF SSAR GRANTS-IN-HERPETOLOGY

The SSAR Committee on Grants-In-Herpetology, at the SSAR annual meeting in Milwaukee during August 1980, announced the recipients of SSAR grants for 1980. Awards were made in three of the four categories for these grants (no zoo research proposals were received in 1980). The categories to which grants were made were: Conservation, Graduate Student Research, and Regional Herpetological Society proposals. The recipients were:

Conservation: ($300.00)	
Richard Seigel	$225.00
Michael W. Klemons	75.00
Graduate Student: ($300.00)	
Richard B. King	175.00
Jonathan A. Campbell	75.00
Joseph C. Mitchell	25.00
Lawrence L. Woolbright	25.00
Regional Herpetological Society ($300.00)	
Kansas Herpetological Society	200.00
Wisconsin Herpetological Society	100.00

The Society extends its congratulations to the recipients, and encourages interested individuals and organizations to submit their proposals now for the 1981 awards to: Martin J. Rosenberg, Department of Biology, Case Western Reserve University, Cleveland, Ohio 44106. ●

CARTER WINS 1980 SSAR KENNEDY AWARD

The 1980 Kennedy Award Committee has determined that the paper "Structure and Function of the Subcutaneous Lymph Sacs in the Anura (Amphibia)," authored by David B. Carter, was the best student paper published in Volume 13 (1979) of the *Journal of Herpetology*. For his efforts the author was recognized and awarded a $100 check at the SSAR business meeting in Milwaukee, WI, 8 August 1980.

I gratefully acknowledge the members of the 1980 Committee consisting of Robin Andrews, Bill Brown, Alan Channing, and John Iverson for their service.

Michael V. Plummer, Chairman
Kennedy Award Committee ●

MONEY FOR RESEARCH IN THE FEDERAL ENDANGERED SPECIES PROGRAM

Although it may seem otherwise when permits are required, there is a good deal more to the endangered species program than lists, permits, and bureaucratic paperwork. There is money: money for status surveys, summer salaries, basic research, and development of conservation and management programs. Because few individuals are seemingly aware of such funds, this paper provides a brief introduction, as well as a reference, to the availability of funds in the Federal Endangered Species Program.

There are two main sources of contract money involving the Fish and Wildlife Service Endangered Species Program: from Cooperative Agreements with individual states under Section 6 of the Endangered Species Act of 1973, and through direct grants from the Office of Endangered Species in Washington (primarily) or from one of six Regional Offices located in Boston, Atlanta, Twin Cities, Denver, Albuquerque, and Portland, Oregon (secondarily). The Cooperative Agreement program has been reviewed in detail (Anon., 1979a, 1979b) so I will not review it again here. Copies of these references may be obtained by writing to Ms. Dona Finnley, editor, *Endangered Species Technical Bulletin*, U.S. Fish and Wildlife Service, Washington, D.C. 20240. In brief, this program allows the allocation of two-thirds Federal matching funds for every one-third state funds directed toward the conservation of resident species. Table 1 provides a list of states which have signed a Cooperative Agreement with the Fish and Wildlife Service and the total Federal allocation since the Agreement program began. Not every dollar shown has been for research; much involves law enforcement, habitat acquisition, and employee salaries. However, a considerable amount remains for research on the status, distribution, life histories, and potential threats to various species. The species studied do not have to be on the Federal List of Endangered and Threatened Wildlife and Plants, but their survival must be of concern to state authorities. With regard to amphibians and

reptiles, Table 2 provides a list of Federal funds allocated by the states to the study and conservation of various species between 1976 and 1980.

The amount of money authorized for appropriation under the Cooperative Agreement program is set by Congress. In the past, some states have received a disproportionately large share of funds because few states had signed Agreements. However, as more states enter the program, money can be more equitably distributed. In the fiscal years 1981 and 1982, up to $12 million has been allocated to this program.

The Division of Federal Aid in the Fish and Wildlife Service administers the Federal Endangered Species Grant-in-Aid Program. However, the projects selected for funding are initially determined by the states themselves and are reviewed by the Division of Federal Aid to determine if they are in accordance with criteria set for funding. Therefore, individuals who desire more information about how to acquire research money through the Cooperative Agreement program should contact the department of their state wildlife agency that administers non-game activities. Questions about Fish and Wildlife Service involvement with the Cooperative Agreement program should be directed to: Division of Federal Aid, U.S. Fish and Wildlife Service, Washington, D.C. 20240 (phone 703-235-1526).

The Office of Endangered Species accepts unsolicited proposals for research on the biology and conservation of species that are federally listed or which may be candidates for the Federal list. There no set format for such proposals although all should be titled, discuss the application of research to conservation of the species in question, present a review of pertinent literature (if applicable), present an itemized budget, and give an account of the principal investigator's qualifications. Requests are best kept below $10,000, and should never include unnecessary items.

When a proposal is received, it is assessed as to its scientific merit and accuracy, the qualifications of the researcher(s), and how it fits in with the priorities and needs of the Fish and Wildlife Service. The proposal is reviewed by various scientists both within and outside of the Fish and Wildlife Service, the Regional offices (as necessary), Recovery Teams, and anyone else deemed appropriate. The review process can be very quick but, in general, can take many months. All requests should be submitted at least 6 months prior to the desired starting date and preferably earlier. Requests then fall into 3 categories: those accepted and funded, those rejected, and those accepted but whose funding is delayed pending the receipt of additional moneys to the program, if available, such as year-end money. It is best to submit proposals at the beginning of the fiscal year (October-November) instead of waiting until May or June when money for research contracts is usually committed. Money for contracts, like the issuance of permits, rarely coincides with the biological activity patterns of the animals to be studied.

Table 1. States with Cooperative Agreements and total Federal funds ($1,000's) allocated 1976-1980.

Alaska	30.0	Montana	30.0
Arkansas	304.4	Nebraska	93.4
California	4,448.0	Nevada	30.0
Colorado	2,949.5	New Hampshire	25.0

Table 3. Research grants on amphibians and reptiles awarded by the Endangered Species Program, 1979-1980.

Amount	Title
$ 9,986.	The status of the Plymouth red-bellied turtle, *Chrysemys rubriventris bangsi*, from Plymouth, Massachusetts.
2,892.	An assessment of *Caiman latirostris* and *Caiman crocodilus yacare* in northern Argentina.
15,000.	Support for World Conference on Sea Turtle Conservation.
9,688.	Distribution and population status of the ringed sawback (*Graptemys oculifera*), blotched sawback (*Graptemys flavimaculata*), and black-knobbed sawback (*Graptemys nigrinoda*) in Alabama and Mississippi.
45,490.	Investigation of the reproductive ecology, captive propagation and restocking potential of the eastern indigo snake.
10,000.	The status and distribution of *Nerodia harteri paucimaculata*.
5,000.	A survey of the present distribution of the desert tortoise (*Gopherus agassizi*) in Arizona.
20,000.	Surveillance of the crocodile population near Turkey Point, Florida, 29 July to 31 December 1979.
4,000.	Distribution of the Pine Barrens treefrog in Florida.
4,000.	Distribution and population status of the Alabama red-bellied turtle (*Pseudemys alabamensis*).
21,878.	Captive propagation and release program for the Houston toad.
10,000.	Autecology of the Bolson tortoise, *Gopherus flavomarginatus*.
10,000.	Continuation of studies on the Plymouth red-bellied turtle.
1,000.	Leatherback turtle survey in the Dominican Republic.
28,000.	Effect of incubation temperature on sex of hatchling Pacific ridley (*Lepidochelys olivacea*) and Pacific green (*Chelonia mydas agassizii*) turtles.
34,000.	Biological studies directed to the conservation of olive ridley sea turtles.
6,000.	Living tags for hatchling sea turtles.

In addition to the Washington office, each Regional office may fund some contracts, although they are limited by the generally smaller amounts of money available. The Regions also fund proposals more in line with their own immediate needs, and therefore are more likely to solicit individuals to perform needed work. A list of research proposals for amphibians and reptiles approved by the Office of Endangered Species during 1979-1980 is provided in Table 3 to give an idea of the type of grants and the amounts which have been funded in the past. All grant requests should be submitted to: Director/ OES, U.S. Fish and Wildlife Service, Washington, D.C. 20240. Questions concerning the grant program should be directed to Mr. Amos Eno at the Office of Endangered Species (phone 703-235-2407).

ACKNOWLEDGEMENTS

I thank Dona Finnley and James D. Williams for providing information and comments on the manuscript.

HERPETOLOGY AT THE SAVANNAH RIVER ECOLOGY LABORATORY

The Savannah River Ecology Laboratory (SREL) is staffed and operated by the University of Georgia. The laboratory is located near Aiken, South Carolina, on the Savannah River Plant (SRP), a 300-square mile tract of land owned by the United States Department of Energy. A unique feature of the site is that it is completely isolated from the public for security reasons. Thus, long-term and extensive field studies are possible with minimal concern for any type of disturbance to study sites or equipment.

The SRP is located in the Upper Coastal Plain and has a diversity of natural and man-made aquatic and terrestrial habitats which provide a unique opportunity for field studies. Among the terrestrial habitats are pine and hardwood forests, turkey oak stands, upland sandhills, and cypress-black gum forests along the Savannah River. The U.S. Forest Service manages part of the land for timber so that a succession of habitat types from clear-cuts to 30-year-old pine stands can be found.

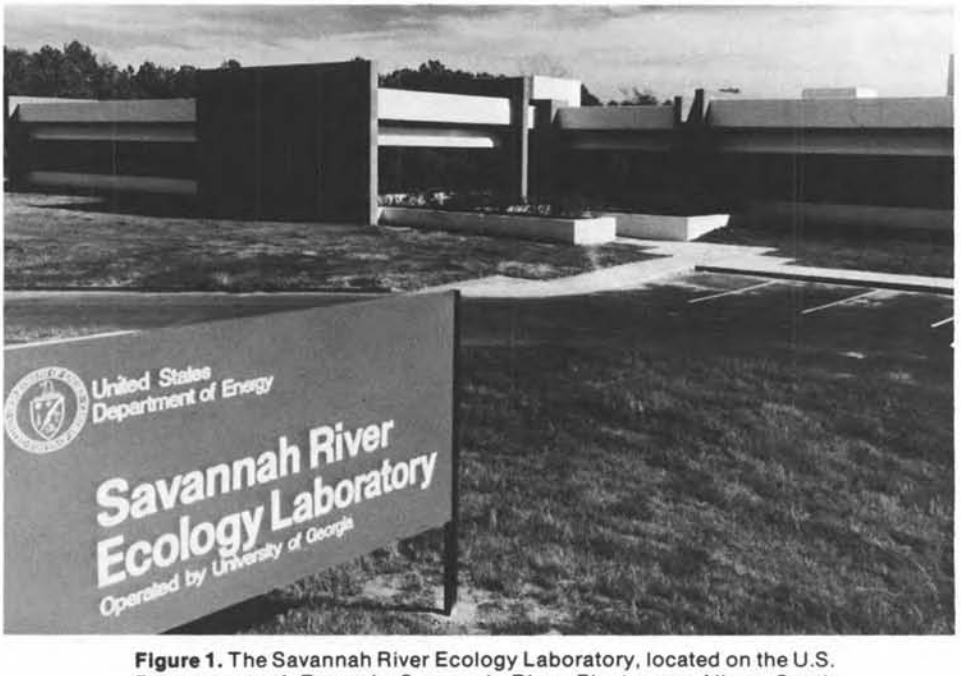

Figure 1. The Savannah River Ecology Laboratory, located on the U.S. Department of Energy's Savannah River Plant near Aiken, South Carolina.

Aquatic habitats include ponds, small lakes, blackwater streams, springs, the Savannah River, and a 3000-acre reservoir. Carolina bays, the unique lentic habitats of the southeastern Atlantic Coastal Plain, are common on the SRP and are represented by several dozen of various sizes.

The diversity of habitat types on the SRP in combination with a rich herpetofauna is proving valuable in field studies of reptiles and amphibians. Research, both field and laboratory, is carried out by SREL's resident staff, graduate and undergraduate students, and visiting faculty.

Most ecological research on reptiles and amphibians of the SRP has been conducted within the last decade. In fact, with the exception of a general survey in the early 1950's by W. H. Freeman and a single paper in *Herpetologica* by E. D. Bellis in 1964, the first ecological studies in herpetology on the SRP did not emerge in the literature until 1968.

Herpetologists in residence at SREL at this time are: J. Whitfield Gibbons (who is also Associate Director) and Janalee P. Caldwell. Other staff members at SREL who conduct studies on amphibians and reptiles include Michael H. Smith (Director) and I. Lehr Brisbin.

Figure 2. Jan Caldwell and Garfield Keaton check a drift fence and record information on a marked population of turtles. Several populations of turtles and amphibians on the SRP are the focus of long-term capture-recapture studies.

Whit Gibbons is continuing his long-term studies on the population biology of aquatic turtles of the SRP. Several thousand individuals from numerous populations are now marked. Many recaptures are of animals that were originally captured 10-13 years ago. In his studies, which address evolutionary and ecological questions, sampling and monitoring techniques include drift fences and pitfall traps, radiotelemetry, and X-ray photography, as well as more conventional methods. Working with him on the turtle projects is Judy Greene who first demonstrated the effectiveness of X-ray photography in reproductive studies. Garfield Keaton is actively involved in these turtle studies and is concentrating on orientation and terrestrial migratory phenomena of all local species. Dr. Justin Congdon recently joined the SREL postdoctoral staff to work on the turtle projects under Gibbons' recently funded NSF grant. In addition to the turtle research, Gibbons is also analyzing earlier-collected data sets from herpetological studies. These include examination of reproductive and activity cycles of local snakes from collections of more than 2000 road-killed animals and analysis of amphibian activity cycles based on samples collected at several drift fences. Involved in the analysis and interpretation of certain aspects of these data are Pat Murphy, Karen Patterson, Ray Semlitsch, Joe Schubauer, Judy Greene, and Garfield Keaton.

Jan Caldwell's research interests center around amphibian population biology. In addition to continuing studies on antipredator mechanisms and survival in tadpole populations, she is in the second year of a long-term study on population biology of several species of frogs and salamanders which breed in Carolina bays. Two bays are enclosed by drift fences and all animals moving in and out (more than 80,000 captures in the first year) are collected and individually marked so that various life history parameters can be examined. Ray Semlitsch is involved in these studies and, additionally, is using radioactive tags (Tantalum-182) to monitor the terrestrial activity of *Ambystoma talpoideum*. Gary Moran and Cindy Shoemaker provide technical help on these projects. In addition, Gary is analyzing data collected by means of the drift fences to establish whether individual frogs and salamanders migrate to and from the bays using the same corridors.

The primary herpetological focus of I. Lehr Brisbin has been on bioenergetics of reptiles. One long-term study has been a determination of energy budgets of captive kingsnakes; total caloric intake (feeding) and production (growth) have been measured in some specimens for over 13 years. Brisbin has also investigated behavioral responses of alligators in a large reservoir to thermal effluents from SRP nuclear reactors. In these studies, Brisbin and University of Georgia graduate student Tom Murphy capitalized on thermal aquatic gradients on the SRP by using radiotelemetry to examine fall and winter movement patterns of individuals during periods when the species is normally dormant.

Figure 3. Kent Brown (left), graduate student from Texas Christian University, and Steve Bennett, graduate student from the University of Georgia, use the drift fence technique in their studies of the effects of various land management practices on the herpetofauna.

Figure 4. An albino *Kinosternon subrubrum* collected as a hatchling on the Savannah River Plant.

Mike Smith's herpetological research has centered around genetics questions and the revelation of genetic patterns through the use of electrophoresis. He has completed or has in progress major projects with certain freshwater and sea turtles, Puerto Rican frogs, and the American alligator.

Graduate student projects have been a major contribution to the research output of SREL. More than a dozen doctoral and master's theses have been based on herpetological field studies on the SRP. Recently completed theses include Karen K. Patterson's studies of paedogenesis in *A. talpoideum*, Thomas M. Murphy's research on the ecology of alligators, Robert Parmenter's examination of diet selection in aquatic turtles, and Patricia Murphy's determination of the orientation capabilities of juvenile alligators. Several other theses are in the final stages. Edward Standora carried out an extensive investigation of thermoregulatory phenomena in alligators and turtles. Besides the biological findings that will come from this work, Standora's contribution to the design and utilization of microtelemetry should prove to be outstanding. Joseph P. Schubauer has completed his research on movement patterns of aquatic turtles in the heated reservoir system where he successfully monitored the movement of more than 30 *Pseudemys scripta* equipped with radio transmitters. William Etges has finished his research using electrophoretic techniques on 14 species of frogs on the SRP to establish the relationship between genetic patterns and environmental variability. Other graduate student projects in progress at this time are those of Stephen H. Bennett and Kent L. Brown. Both are using the drift fence and pitfall trap sampling technique to address questions of how land management programs of the U.S. Forest Service influence the herpetofauna.

SREL also has an active program of research participation for undergraduates. Most students spend 10-12 weeks in residence at SREL, usually in the summer, and work under the direction of a particular senior staff member. SREL graduate and undergraduate students are from various schools throughout the country: Standora, Etges and Bennett are

Figure 5. Joe Schubauer and Ed Standora, graduate students from the University of New York at Buffalo and the University of Georgia, respectively, fit a turtle with a transmitter for use in studies of movement and thermoregulation.

from the University of Georgia; Schubauer is from the State University College at Buffalo; Brown is from Texas Christian University.

SREL has a visiting faculty research program whereby faculty members from any institution may apply to conduct research for a short period (several weeks) or for as long as a year (sabbatical leave). During the past few years, several herpetoogists have worked on field projects at SREL. The following is a partial list including the nature of their research: Robert D. Aldridge, St. Louis University, Reproductive cycles of temperate zone snakes; Donald L. Moll, Southwest Missouri State University, Comparative feeding relationships among freshwater turtles; Gary Ferguson, Texas Christian University, Ecological and evolutionary aspects of lizard populations; Donald W. Tinkle, University of Michigan, and Royce Ballinger, University of Nebraska, Comparative demography of lizard populations; Ronn Altig, Mississippi State University, Ecology and morphology of anurans; James Spotila, State University College at Buffalo, Thermoregulation and climate space modeling of large reptiles.

Visitors, including faculty with classes on herpetology field trips, are welcome at SREL within certain limitations. Anyone contemplating a visit to SREL and the adjacent field sites should be aware that a visitor's security badge is necessary to gain entrance to the area. In addition, any visitors to the field must be U.S. citizens and be accompanied at all times by someone on the SREL staff. Field groups cannot visit the SRP without having made prior arrangements for such escort. While it is not difficult to obtain badges for U.S. citizens, a 10-day notice is required for those wishing to go into the field. Visitors who are U.S. citizens can tour the laboratory facilities without advance notice.

MORE ON BIPES

THERE IS NO EVIDENCE THAT *BIPES* OCCURS IN THE U.S.

Campbell (1980, Herp Review 11(1):6-7) has resurrected the early observations of a two-legged lizard on the South Platte river, perhaps between Ogallala, Nebraska and Julesburg, Colorado. He has suggested that the assignment of the name *Chirotes* by professional zoologists was sufficient indication that the collectors were dealing with an amphisbaenian. Negative evidence is never satisfactory. As amphisbaenians (though members of a different family,) once inhabited the American West it is possible that some forms survived. However, evidence for their occurrence should be stronger than that now available.

The key factor in the original description seems to be in the statement "they were so active, that it was not without some difficulty that we succeeded in obtaining a specimen" (James, 1823). We have collected and handled a goodly number of amphisbaenians and have never found any difficulty in catching them once they were disclosed. Almost all known species and particularly *Bipes* move relatively slowly; even when trogonophids go into their saltatory escape behavior there is no problem in catching them. Furthermore, the known species of *Bipes* are almost never found active on the surface. During field studies on *Bipes*, in which over 3000 individuals were encountered, all except three were dug up from underground. These three were found crawling slowly on the surface at night. Whatever the animal observed by James, it is most unlikely to have been an amphisbaenian.

Secondly, reference to the Cuvierian name *Chirotes*. In 1820 the forms in question were still in a major state of confusion. It was not until some years later that the affinities of the several two-legged and limbless amphibians and reptiles were sorted out by Müller. Consequently the suggestion that *Bipes* was misidentified by Edwin James or Thomas Say does not insult their memory; it is remarkable that these early explorers did as well as they did.

As there is no other direct observation, and all "reports" of *Bipes* from the central U.S. followed rather than preceded local inquiries for such animals, it seems best to delete such "records" from future field guides.

A COMMENT ON J. HOWARD CAMPBELL'S *BIPES* REPORT

Campbell's (1980) speculation that reports of *Bipes* in Nebraska or Colorado might be valid brings to mind my experience with a report of relatively recent vintage. On June 11-12, 1951, I was collecting in Brady County, Nebraska, 21 miles north of North Platte along U.S. Highway 83, in the so-called Sandhills region. At that time U.S. 83 ceased to be a paved road just north of my collecting sites and became an unmarked sandhills trail, one in which a car could easily bog down in loose sand. I had collected specimens of three lizard species, *Sceloporus undulatus, Holbrookia maculata,* and *Eumeces multivirgatus* and while searching on the ranch of A.J. Simants of Tryon, Nebraska, I had a chat with Mr. Simants and his children. They claimed that—and I quote my field notes—"There is in this area a lizard with only two legs, these near the head. It is said to crawl like a snake and reaches a length of a foot or so. Grayish or silvery grayish in color. Found along fence rows or fence posts." One of the Simants' children, a lad of about 13, described the other lizards of the area accurately enough so that without him seeing my catch I was convinced that he recognized the conventional lizards that were to be found there. He also seemed to know the various snakes of the area. I recall also that the young man accompanied me to some refuse piles and told me that they were most apt to encounter the "two-legged lizard" when excavating for fence posts or when pulling up rotting fence posts.

My notes also state, "Here again we hear of an amphisbaenid-like animal in Nebraska. Could it be?" I do not recall my source of knowledge of amphisbaenid reports but suspect it came from Taylor's (1938) note. Thus to return to the idea of present day existence of amphisbaenids in Nebraska I note that geologists claim that the Sandhills were a refugium during the Pleistocene. Admittedly the climate then probably was quite cool and moist but summers could have been mild and a fossorial creature could possibly have thrived there. That such a creature could avoid detection today is not surprising; the area is poorly collected and fossorial species are inconspicuous in any event. Even in Florida where *Rhineura floridana* probably is a common species the number of records is few despite extensive collecting activity. Florida collectors have told me that many of the known specimens were discovered as a result of the lizards accidentally falling into man-made, concreted excavations; thus, discovery of the lizard by a herpetologist in the field appears to be an infrequent event. I therefore inclined to concur with Campbell that Edwin James' report may indeed be valid.

A NEW REPRINT

Herpetology of Brazil

COMPRISING THREE BOOKS BY J. B. VON SPIX AND J. G. WAGLER
TOGETHER WITH A NEW INTRODUCTION BY P. E. VANZOLINI (SAO PAULO)

about 400 pages (including 98 plates); 8 1/2 by 11 inches; index

IN 1817 Johann Baptist von Spix and his colleague Karl-Friedrich-Philipp von Martius, a botanist, set out from Bavaria on a three-year exploration of Brazil. Besides collections of plants and other animals, those of amphibians and reptiles provided the most comprehensive and important early survey of the herpetology of Brazil and, indeed, of all of South America. Some 155 species were described, most of them newly discovered, as well as first descriptions of such familiar genera as *Bothrops, Micrurus, Kinosternon* and *Caiman* among others. All species were beautifully illustrated in detailed, full-page plates, one of which is reproduced in color.

This reprint edition includes the original volumes (first published in Munich, 1824-25) plus an extensive new introduction by Professor Vanzolini which gives an itinerary for the Spix-Martius expedition (with map) through the Atlantic forests, the caatingas of northeastern Brazil and up the Amazon River to the Peruvian border. In addition, there is an historical discussion of the expedition; tables of species names with modern equivalents to bring the nomenclature up to date; a detailed review of the type localities; and an announcement of the rediscovery of Spix's and Wagler's type specimens in Munich and Leiden.

to order

SSAR members, if ordered *before November 30, 1980* . . . . $30 clothbound
Institutions; Non-members; All orders after November 30 . $36 clothbound

Prices include packing and shipping, world-wide. All SSAR members must place their orders now to take advantage of the special pre-publication prices. The book will be issued during Winter 1980-81. Send orders to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Make checks payable to "SSAR"; receipt on request. A pricelist of other Society publications can be obtained on request from Dr. Taylor including the *Journal of Herpetology, Herpetological Review, Contributions to Herpetology, Herpetological Circulars, Catalogue of American Amphibians and Reptiles* and pamphlets and other books in the *Facsimile Reprints in Herpetology* series. *Payment in U.S. funds please!*

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The discovery of fossorial creatues can crush our egos when we think that the herpetofauna of a given area is well known—*e.g.* the finding of the remarkable salamander, *Phaeognathus hubrichti*, in Alabama in 1960!

PLEASE RESPOND

The SSAR has taken a stand against H. R. 4805, the "Research Modernization Act." Reasons for this position were outlined in Herpetological Review 11(2):28-29. The proposed legislation may have rather broad reaching ramifications for those conducting research on live animals. Please review the position of the SSAR and immediately write your local congressmen as you deem fit. If you would like a copy of the bill, contact Hugh Quinn, Department of Herpetology, Houston Zoological Gardens, 1513 Outerbelt Dr., Houston, Texas 77030. ●

CURATION OF COLLECTIONS

A report on current supplies and practices used in curation of ichthyological collections appeared recently. This report was put together by an ad hoc subcommittee of the American Society of Ichthyologists and Herpetologists' Ichthyological Collection Committee. The 63 page report summarizes the results of a survey and questionnaire designed to determine the curatorial techniques and procedures used in major ichthyological collections and the products found most useful in their maintenance and curation. In addition, recommendations pertinent to the primary areas covered are included.

The report is divided into six sections and discusses the following topics: Fixation and Preservation, Specimen Containers, Inks and Labels, Collection Environment, Electronic Data Processing, and Compactors. Included in the five appendices are names and addresses of dealers and suppliers that handle the bottles and paper supplies discussed. While some parts of the report are pertinent only to the curation of fishes, much of the information and most of the discussion is equally applicable to the curation of amphibian and reptile collections. Herpetologists responsible for the curation and maintenance of collections would be well advised to read this important and well documented report. It not only provides a ready source of valuable information, but also considers issues and procedures crucial to the long term maintenance of these national resources. Dr. William L. Fink and his committee are to be commended for this timely and well done report. A limited number of copies are available from: Smithsonian Oceanographic Sorting Center, Smithsonian Institution, Washington, DC 20560, Attn: Dr. Leslie W. Knapp. *ASIH-HL-SSAR Joint Committee on Management of Systematic Resources in Herpetology.* ●

NEW 1980 NOW AVAILABLE

VENOMOUS SNAKES OF THE WORLD
A Checklist
KA Harding & KRG Welch

A guide to the nomenclature and distribution of venomous snakes which lists 738 species and sub-species, divided into 85 genera. Each entry gives the original descriptive reference, genotype, specific type, locality, and brief details of the known distribution.
Faunal lists are provided for 137 countries and island groups, with literature references for identification of local species.
The comprehensive index includes selected synonyms and common names and over 570 fully documented taxonomic references.

Contents
Taxonomy: Colubridae. Elapidae. Hydrophiidae. Viperidae. Taxonomic References.
Geographical Distribution: The Americas. Europe. Africa. Asia. Australasia and the Pacific Islands.
Bibliography. Author and Subject Indexes.

Techniques

AN EFFECTIVE METHOD OF PRESERVING LARGE REPTILES

Large reptiles, primarily because of difficulties of injection and storage containers, are rarely preserved whole as museum specimens, despite their obvious usefulness as museum reference materials. Cook (1965) suggested disarticulation and individual preservation of the more conveniently sized portions of the animal. A recent opportunity to preserve a whole Leatherback, *Dermochelys coriacea*, the largest and perhaps the rarest of the marine turtles, resulted in the innovation of a deep injection apparatus, and this plus the storage tank are outlined in this note.

On 11 September 1978, an adult male Leatherback Turtle, *Dermochelys coriacea*, was found entangled and drowned in cod nets by Blair and Robert Clow off Grant Tracadie, Prince Edward Island. The specimen obtained, an adult male, was 2.08 m from snout to tail tip, (1.42 m shell length) and weighed approximately 450 kg. It was placed in a cold storage plant and frozen soon after being landed. Through the cooperation of John Gilhen of the Nova Scotia Museum, the animal was obtained by the National Museum of Natural Sciences. It was shipped to Ottawa by refrigerated transport and held in cold storage.

On the morning of 1 December 1978, the specimen was moved by truck to the taxidermy unit where it was thawed gradually at approximately 10°C. By that afternoon the thin edges of the flipper had become flexible and during the next day formalin (20%) was injected with a 25 cc Luer Lock veterinary syringe (equipped with a 50 mm, 16 gauge needle) into the flippers, eye sockets and superficial muscles of neck and tail, as well as the penis which was frozen everted. Additional injections were were made over the next three days as thawing gradually proceeded. On 6 and 7 December, deeper injections were made to infiltrate most of the animal with formalin as thawing neared completion. Because commercial syringe needles available were too short for deep injections, a suitable needle, 50 cm in length was fabricated from 1/4 inch (= 0.62 mm) steel automotive brakeline. A one-way hand primer bulb (of the type frequently used to prime boat engines) was inserted between two lengths of aquarium tubing. The needle was inserted into the turtle through a small scalpel incision and connected to the outflow tube of the primer bulb. The inflow tube was placed in a 50% formalin solution. By periodically shifting the needle to new sites, approximately 30 l of solution were pumped into the specimen. This means that, if one considered the total volume of the turtle as a fluid, with the 30 l of 50% solution added, it would yield a total solution of approximately 5%. This apparatus (Figure 1), easily constructed from readily available materials, proved very effective for deep injection. It is noteworthy because it could also be as useful for field injection of large specimens.

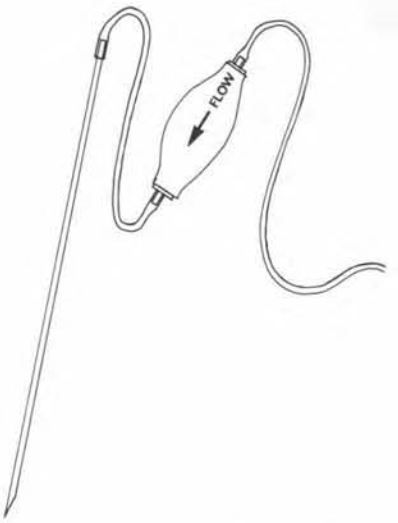

Figure 1. Apparatus used for deep injections.

Permanent storage was possible in a rectangular tank constructed of 2.5 cm plywood, fiberglassed (epoxied) both inside and outside, and reinforced externally with angle iron girdling the tank midway up the sides.

HERPETOLOGICAL
SKELETONS
SKULLS

Prepared for educational and display needs.

Over 1000 specimens in stock. From 2 in. tree frog to 7 ft. monitor lizard and 16 ft. python.

We welcome your requests and inquiries.

Dictionary of Vertebrate Zoology
Russian-English: English-Russian
GEORGE J. JACOBS

"This is not a dictionary of definitions but rather a tool for herpetologists and vertebrate zoologists, to assist their reading of Russian scientific literature on zoological research. While Russian-English dictionaries are available for the biological sciences, this specialized list will enhance the ability of students and scientists to read Russian papers on current natural history studies. The low cost puts it in reach of all. Recommended for university science libraries and recommended especially for individual scientists in the fields of herpetology and vertebrate zoology."—CHOICE

- English-Russian **and** Russian-English biological and anatomical terms.
- **Both** sections list Latin taxonomic terms and Russian common animal names.
- Complete listing of names of scales and bones.

48 pp./9 x 10/0-87474-551-9/$4.25 paper

This tank had been prepared by the Technical Services Division of the National Museums of Canada some years previously in anticipation of the acquisition of a large marine turtle. The specimen after injection was lifted into the tank with block and tackle and the container "topped up" with 1350 l of 20% formalin to totally immerse the specimen. The turtle will be transferred later to 50% isopropyl alcohol.

In the field, large specimens, injected by the method outlined here could be wrapped in some suitable formalin-soaked material, encased in plastic and shipped to a museum for permanent storage.

We are indebted to Terry Morgan and the staff of the Taxidermy Section of the National Museum of Natural Sciences for patience and assistance, and to Franc , Cook who braved preservative fumes to encourage us and help us with the manuscript.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Dept. of Herpetology, Houston Zoological Gardens, Houston, Texas 77001.

CAPTIVE REPRODUCTION IN SONORAN BLACK KINGSNAKES (*LAMPROPELTIS GETULUS NIGRITUS*)

Reproduction data have been recorded for *Lampropeltis getulus splendida* (Wright and Wright, 1957), *L. g. californiae* (Perkins, 1952), and most other members of the *getulus* complex (Wright and Wright, 1957). However, scant reproduction data have been recorded for *L. g. nigritus* since being described by Zwiefel and Norris in 1955. This paper reports captive reproduction of *L. g. nigritus*, with notes on combat behavior.

In 1975 and 1976, the collection of *L. g. nigritus* at the Oklahoma City Zoo consisted of two males and one female. Male A (total length 108 cm, weight 453 g) was acquired February 1973; male B (total length 117 cm, weight 424 g) and the female (total length 98 cm, weight 211 g) were both acquired July 1974. All three were uniformly black dorsally with varying amounts of white ventral markings. Blaney (1977) described the pattern of *L. g. nigritus* as ranging from uniformly black both dorsally and ventrally to a reduced *L. g. splendida* pattern. He adds that the anal plate is always light colored.

The three adults were housed on exhibit in a plywood cage measuring 72 x 59 x 43 cm. The glass fronted enclosure was covered at the top with ¼ inch hardware cloth. The substrate consisted of sand with rocks for cover. Plastic plants decorated the enclosure. Lighting was supplied by two 75 watt Vita-lite flourescent bulbs (Duro-test Co.) suspended approximately 44 cm above the top of the enclosure.

Though no copulation was observed, breeding was believed to have first occurred in 1975, as on 9 June 1975, the female laid a clutch of four eggs. The young emerged from the eggs 59 days later (Grimpe, 1975).

Male A was removed from the enclosure in fall 1975 and placed in a plastic reserve cage alone. The reserve cage was kept in a separate part of the building, away from the exhibit cage. Male B and the female were left on exhibit throughout the winter.

On 7 March 1976, male A was reintroduced into the exhibit cage containing the pair of *L. g. nigritus* and combat behavior between the two males occurred immediately. During combat, both males crawled about the cage with their bodies intertwining as each attempted to place his fore body above his rival's. Periodically, biting was employed on the forward dorsal aspect of the rival. Shaw (1951) described similar combat behavior in *Lampropeltis triangulum annulata* as well as in members of the genus *Pituophis*.

L. g. nigritus Male A, appeared to exhibit dominance by the criteria of Carpenter and Gillinham (1977), as he maintained a posture of superiority and aggressiveness most frequently.

At 1430 hr. on 7 March 1976, male A was observed in coitus with the female. Coitus lasted more than two hours; male B generally remained in another portion of the cage. No further copulation was observed.

For several days following the observed copulation, both males were found with new superficial skin abrasions, indicating continued combat. This may also have been an indication that both animals, at times, exhibited dominance.

Fig. 1. Faintly patterned juvenile *Lampropeltis getulus nigritus.*

Fig. 2. Juvenile *Lampropeltis getulus nigritus* exhibiting *L. g. splendida* type pattern.

Several days before egg laying, the female, which had refused food for several weeks, began showing an increase in girth. She was placed in a reserve cage containing damp sphagnum to accomodate egg laying. On 16 April 1976, she laid five eggs (Table 1).

The eggs were incubated in damp sphagnum, contained in a crockery bowl. The bowl and eggs were sealed in a plastic bag which was opened approximately every other day to replenish oxygen. The temperature of the room in which the eggs were incubated generally fluctuated 27-32° C.

On 13 June 1976, after an incubation time of 59 days, all five young hatched. Total lengths and weights of the young were recorded (Table 2). Lengths were measured as described by Quinn and Jones, 1974. Measurements of young could not be correlated with their corresponding eggs, as the young emerged from the eggs unobserved.

The young varied in pattern considerably, from an almost totally black specimen with white markings on the underside (Fig. 1) to one that had exhibited a pattern similar to that of an adult *L. g. splendida* (Conant, 1958) (Fig. 2). Within two years ontogenetic changes reduced the pattern almost completely.

Table 1. Egg measurements for *Lampropeltis getulus nigritus*.

Egg #	Diameter (cm)	Length (cm)	Weight (g)
1	2.4	6.1	Total weight of egg clutch
2	2.2	5.7	113.3 (x = 22.7)
3	2.2	6.8	
4	2.3	5.5	
5	unavailable	6.5	

Table 2. Length and weights of newborn *Lampropeltis getulus nigritus*.

Young #	Total Length (cm)	Weight (g)
1	32.1	17.0
2	32.6	17.7
3	34.7	18.8
4	31.9	17.1
5	34.3	17.7

ACKNOWLEDGMENTS

I wish to thank Mike Blakely and the reptile staff at the Oklahoma City Zoo for their assistance. I am also grateful to Hugh Quinn and John Werler for critically reviewing the manuscript, as well as to Debbie Butler for typing it.

NEWSNOTES

BIOSIS TO COPUBLISH ZOOLOGICAL RECORD

Responsibility for the publication of **Zoological Record**, which annually indexes research reports appearing in over 6,000 journals in the animal sciences, will be assumed by BIOSIS beginning with Volume 115. **Zoological Record** has been published by the Zoological Society of London since 1864.

Under the new agreement, **Zoological Record** will be jointly published by BIOSIS and the Zoological Society. An Advisory Board will be formed under an independent chairman with equal repesentation from BIOSIS and the Zoological Society. Editorial Policy will be under the direction of an editor who will be appointed by the Zoological Society. ●

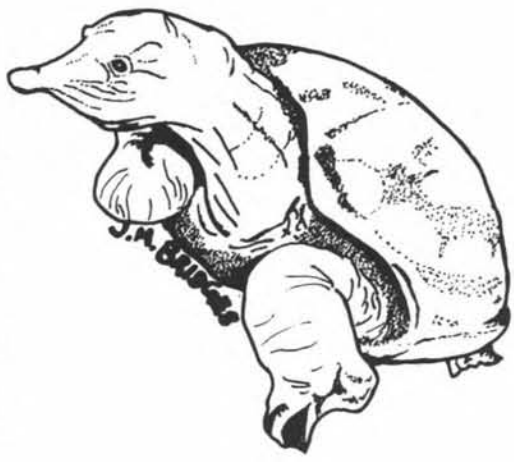
BOOK ANNOUNCEMENT

The Chihuahuan Desert Research Institute announces the availability of Contribution No. 87, "A Life History Study of the Gray-banded Kingsnake, *Lampropeltis mexicana alterna*, in Texas" by Dennis J. Miller.

This 55 pp. report includes 5 photos, 11 distribution maps, and 5 tables and charts. Topics covered include morphology, geographic distribution, definition of habitat, behavior, food, reproduction, mortality, husbandry, and the status of the Gray-banded Kingsnake as a non-game protected species.

Soft-bound copies are available at a cost of $5.00 ea. (Texas residents include 5% tax) from: The Chihuahuan Desert Research Institute, Box 1334, Alpine, Texas 79830. Include 50¢ for postage and handling. ●

PROPOSED ENDANGERED TURTLES



The following is from **FR** 45(138):47715.

As amended November 10, 1978, the Endangered Species Act mandates withdrawal of proposed rules to list species which have not been finalized within two years of the proposal. The amended Act also authorized a one-year suspension of all withdrawals, until November 10, 1979. The time limit has expired for the Key mud turtle (*Kinosternon bauri bauri*) which was originally proposed for listing as Endangered with Critical Habitat on May 19, 1978 (43 FR 21072-75). The Plymouth red-bellied turtle (*Chrysemys rubriventris bangsi*) which was proposed as Endangered with Critical Habitat in the same proposal was made final on April 2, 1980 (45 FR 21828-33). This notice constitutes the withdrawal of the Key mud turtle listing proposal.

●

RESEARCH REQUEST

John B. Iverson (Department of Biology, Earlham College, Richmond, Indiana 47374) is compiling a review of reproductive data for all possible turtle species as part of his continuing studies of turtle reproduction and reproductive strategies. Communications sharing unpublished reproductive data, especially for non-North American species and/or species rarely studied or reported upon would be greatly appreciated. All information so obtained will be cited as "personal communication" and duly acknowledged. ●

ANNUAL MEETING PHOTOS SOUGHT

The SSAR archives lack group photos from the annual meetings at Mt. Lake, Carbondale, Kansas City, Albuquerque, Lake Texoma, Auburn, Fullerton and Tempe. Persons who have these photos and would be willing to donate them should contact Henri Seibert (see inside front cover). The donation will be greatly appreciated. ●

DO YOU HAVE HOUSTON TOADS?

The Houston Toad Recovery Team is in the process of gathering information concerning *Bufo houstonensis*. Anyone having specimens or skeletal material of Houston toads is requested to send collection data to:

R. A. Thomas
Louisiana Nature Center
11000 Lake Forest Blvd.
New Orleans, LA 70127 ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

ANURA
CAUDATA

GASTROPHRYENE CAROLINESIS (Eastern Narrowmouth Toad). USA: KANSAS: Cherokee Co: 4.8 km S, 0.8 km W Lawton. 29 April 1972. V. E. Jones. Verified by Joseph T. Collins, Univ. Kansas Mus. Nat. Hist. Deposited in Museum of the High Plains (MHP 6081). Third known specimen from Kansas. The other two are as follows: Cherokee Co: 6.4 km N Baxter Springs. 27 April 1947. Edward Beasley (KU 24414); and Cherokee Co: 4.8 km N Galena. 24 April 1950. Irving Baird (KU 28622).

Submitted by **MICHAEL S. RUSH** and **EUGENE D. FLEHARTY**, Department of Biological Sciences, Fort Hays State University, Hays, Kansas 67601. ●

TESTUDINES

CHRYSEMYS NELSONI (Florida Redbelly Turtle). USA: GEORGIA: Ware Co: Okefenokee Swamp, Moonshine Ridge, 1.1 km N. Florida state line, 2.0 km W. Charlton County line. 28 April 1980. Two juveniles and one adult seined from small swampy area. Adult preserved (UGAMNH 07762). First record for state and extends range approximately 24 km north of previously recorded localities (Carr and Crenshaw. 1957. Bull. Florida St. Mus., Biol. Sci. 2: 25-42; Powers, A. 1977. Geographic distribution: *Chrysemys nelsoni.* SSAR Herp. Review 8(3):84).

Submitted by **LAURIE J. VITT**, Museum of Natural History, University of Georgia, Athens, Georgia 30602 and **ARTHUR E. DUNHAM**, Leidy Laboratory of Biology, University of Pennsylvania, Philadelphia, Pennsylvania 19104. ●

CLEMMYS GUTTATA (Spotted Turtle). USA: GEORGIA: Lee Co: 12.1 km N Leesburg on Ga. Rt. 377. 7 May 1976. Norman Bevan. Verified by V. N. Powders. Georgia Southwestern College Museum (GSCM 1643). Calhoun Co: Edison. 17 April 1975. B. McKinney and R. Bracken. Verified by R. H. Mount. Auburn University Museum (AUM 26741). New county records and confirms presence of species in southwestern portion of state, previous record near Albany being questionable (Conant, 1958, A field guide to reptiles and amphibians, Houghton Mifflin Co.).

Submitted by **CARLOS D. CAMP**, Department of Zoology-Entomology, Auburn University, Auburn, Alabama 36830, and **VERNON N. POWDERS,** Department of Biology, Northwestern Oklahoma State University, Alva, Oklahoma 73717. ●

PSEUDEMYS SCRIPTA ELEGANS (Red-eared slider). USA: Indiana: Harrison Co: 11.6 km south of Corydon on HWY 135. 22 April 1978. Adult male. J. Harry Reynolds Jr. Verified by Michael Seidel, N. Bayard Green Museum, Marshall University. Specimen deposited Carnegie Museum (CM 74019). First county record and extends range *ca.* 75 km southeast of the reported range in southern Indiana (Minton, S. A., Jr. 1972. The Reptiles and Amphibians of Indiana. Ind. Acad. Science.). A dead, adult specimen was also found *ca.* 14.2 km east of the above locality in an isolated farm pond 4.4 km north of Elizabeth, Harrison County, Indiana in May 1979 by S. L. Reynolds, but was not collected.

Submitted by **J. HARRY RENOLDS JR.**, 1516 Shelby Place, New Albany, Indiana 47150, and **SAMUEL L. REYNOLDS**, N. Bayard Green Museum, Department of Biological Sciences, Marshall University, Huntington, West Virginia 25701. ●

RHINOCLEMMYS PULCHERRIMA PULCHERRIMA (Mexican Wood Turtle). MEXICO: OAXACA: 8.0 km N. Pochutla on Hwy. 175. 16 June 1979. J. B. Iverson, P. Meylan, and D. Gicca. Verified by J. B. Iverson. Florida State Museum (UF 45984). Fresh DOR, 1125 hrs CST. Extends range of subspecies eastward ca. 130 km along Pacific coast and narrows hiatus in range between *R. p. incisa* and *R. p. pulcherrima* to less than 90 km (Ernst, 1980, Cat. Amer. Amph. Rept. 1-2; Smith and Smith, 1980, Synopsis of the herpetofauna of Mexico, Vol. VI. Guide to Mexican Turtles, John Johnson, North Bennington, Vermont).

Submitted by **JOHN B. IVERSON**, Department of Biology, Earlham College, Richmond, Indiana 47374. ●

SAURIA

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). USA: FLORIDA: Collier Co: Naples. 4 March 1980. W. B. Hadley. Verified by J. C. Mitchell. U. S. Nat. Mus. Nat. Hist. (USNM Herp Field Number 112974). Specimen was found in a hospital; several others observed locally. New county record and first record for mainland of west coast Florida. This locality lies 40 km SE Sanibel Island record (McCoy, C. J. 1972. SSAR Herp. Review 4(1):23). Myers (1978. SSAR Herp. Review 9(3):107 and 1979. SSAR Herp. Review 10(3):102-103) and McCoy (1972, SSAR Herp. Review 4(1):23) review east coast localities.

Submitted by **JOSEPH C. MITCHELL**, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916 (mailing address: 1716 Rockwood Rd., Richmond, Virginia 23226) and **WILLIAM B. HADLEY**, 453 Ingraham Street, Naples, Florida 33940. ●

SERPENTES

CROTALUS SCUTULATUS SCUTULATUS (Mojave Rattlesnake). USA: TEXAS: Brewster Co: 33.6 km E Marathon on US Rt. 90. 8 August 1978. Fred Kraus and Gordon W. Schuett. UMMZ 169868. Extends range 34.6 km to the east (see Jacob, J.S. 1977. Southwest. Nat. 22(4):469-485.). The characters observable on the specimen (found DOR) conform with those of *C. s. scutulatus* as designated by Jacob (1977). The minimum number of scales between the supraoculars is two, the average width of the black tail bands is 2.6 scales, the average width of the white tail bands is 4.0 scales, the black band: white band ratio is 0.65.

Submitted by **FRED KRAUS** and **GORDON W. SCHUETT**, Department of Biology, University of Toledo, Toledo, Ohio 43606. ●

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: TEXAS: Swisher Co: on US Rt. 87, 3.2 km N St. Rt. 214 junction. 30 August 1979. Gordon W. Schuett and Fred Kraus. Collected DOR. UMMZ 169870. First record for Swisher County (Raun, G. and F. Gehlbach, 1972, Dallas Mus. Nat. Hist., Bull. no. 2, part 1).

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS**, Department of Biology, University of Toledo, Toledo, Ohio 43606. ●

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). USA: TEXAS: Gray Co: 62.4 km W Oklahoma-Texas state line on US Rt. 40. 29 August 1979. Fred Kraus and Gordon W. Schuett. UMMZ 169867. First record for Gray County (Raun, G. and F. Gehlbach, 1972, Dallas Mus. Nat. Hist., Bull. no. 2, part 1).

Submitted by **FRED KRAUS** and **GORDON W. SCHUETT**, Department of Biology, University of Toledo, Toledo, Ohio 43606. ●

PITUOPHIS MELANOLEUCUS MELANOLEUCUS (Northern Pine Snake). USA: TENNESSEE: Shelby Co: *ca.* 2 km N Millington. 24 November 1979. Richard A. Smith. Identified by J. S. Jacob, verified by M. V. Plummer (Harding University). Memphis State University Museum of Zoology (MSUMZ A1579). Partly digested pine snake removed from stomach of road-killed, adult female coyote (*Canis latrans*). First record for county, third locality in state west of Tennessee River. Extends range *ca.* 120 km SW of nearest known locality (Henderson County). The exact locality for this specimen is in question considering its source, but it apparently came from the north-central Shelby County area since digestion in wild canids may occur in 6 hours or less (Mech, D. L. 1970. The wolf: the ecology and behavior of an endangered species, Amer. Mus. Nat. Hist., The Nat. Hist. Press, Garden City, NJ) and female coyotes have a home range of *ca.* 16 km² (Berg, W. E. and R. A. Chesness. 1978. Ecology of coyotes in northern Minnesota. Pages 228-247 in M. Bekoff (Ed.), Coyotes: biology, behavior, and management. Academic Press, New York).

SISTRURUS CATENATUS EDWARDSI (Desert Massasauga). USA: TEXAS: Ward Co: 9.6 km N Grandfalls on Texas Rt. 18. 30 August 1979. Gordon W. Schuett and Fred Kraus. Collected DOR. UMMZ 169869. First record for Ward County (Raun, G. and F. Gehlbach, 1972, Dallas Mus. Nat. Hist., Bull. no. 2, part 1).

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS**, Department of Biology, University of Toledo, Toledo, Ohio 43606. ●

DISTRIBUTION AND STATUS OF *VARANUS SALVATOR* IN INDIA AND SRI LANKA

INTRODUCTION

Based on visits to the present and former habitats of *Varanus salvator*, we find that the last major populations of this region occur in Sri Lanka and the Andaman and Nicobar Islands. The only two breeding populations left on the Indian mainland are in the mangroves of Bhitar Kanika Sanctuary, Orissa (an important saltwater crocodile and Ridley sea turtle area), and in the mangroves of the Sunderbans of West Bengal and Bangladesh.

Loss of mangrove habitat to farming, timber and firewood interests have severely reduced its range and the existing populations (except Sri Lanka) are threatened by over-hunting for meat, fat and skin. The skins have traditionally been used to make drums in some areas (Northeast India), but their large size has also served to popularize them in the international skin trade. The meat is readily eaten by many people in Bengal and Andamans, where dogs are employed to run the lizards down. The semi-developed eggs in gravid females are considered a delicacy (the consistency and flavor of an expensive liver paté). The meat is tough, but as palatable as that of other monitors, and the fat is considered of "medicinal" value to be consumed for strength and vigor and to be used topically for muscle and joint pains. In some parts of India, the brightly marked baby monitors ("bis cobra") are considered very venomous, and in Sri Lanka it is believed that water monitor flesh is poisonous. The Singhalese also believe that a deadly poison can be obtained by hanging a dead water monitor up by the tail and collecting the dripping saliva.

FORMER DISTRIBUTION AND ABUNDANCE

There is very little in the literature to indicate the former abundance of *Varanus salvator* in India. To quote M. A. Smith: "Not found in the Peninsula of India except in the extreme northeast, East Bengal and the Eastern Himalayas (up to 6,000 feet); said to be common in the Sunderbans. . . ." It is possible that they were found in the extensive mangroves that once clothed the Malabar coast (now Kerala State) in the extreme southwest. Though there is no direct evidence, it is also possible that they once inhabited several mangrove areas on the east coast (formerly *C. porosus* habitat) namely the deltas of the Krishna and Godavari Rivers in Andhra Pradesh and Pechivaram, Coleroon and Muthupet in Tamil Nadu. Several authors (including M. A. Smith (1973) and E. H. Taylor (1963)) mistakenly reported it from northern Australia (*V. mertensi* is the "water monitor" there). It is hard to confirm whether the rest of this lizard's reported distribution is accurate. Its current occurrence in Burma, Thailand and parts of Malaysia and the "Indochinese" mainland is confirmed, (Smith, 1973; Taylor, 1963) but little else. *Varanus salvator* has a considerably smaller range than once supposed. Its existence in the eastern Himalayas and status in Bangladesh have yet to be investigated.

PRESENT DISTRIBUTION AND ABUNDANCE

On the Indian mainland, the water monitor is found in the two mentioned mangrove habitats in the northeast. The only two substantial populations in the Indian region are in the Bay Islands and Sri Lanka.

1. The deltas of the Mahanadi and Brahmani Rivers in Orissa form a network of creeks and mangrove island totalling about 200 sq. kms. Half of this was designated a Sanctuary in 1976 for the saltwater crocodile, *C. porosus* (total population of possibly 200), and the outlaying sandy islands for the Ridley turtle (over 100,000 nesting *Lepidochelys olivacea* were marked on Wheeler Island rookery in February 1976). Water monitors are evident throughout the area, including the sea turtle nesting beaches, but do not appear to be common. The mangrove area is being harvested for firewood under a Forest Department rotating crop system, but it is also being illegally hacked away by the farmers whose holdings closely surround the sanctuary. Most of the monitors appear very wary, are secretive and bolt upon sighting a human. On the other hand, at the Forest Rest House and Crocodile Rehabilitation Center in Dangmal, several water monitors have reportedly become regular visitors for handouts of fish. The dense mangrove cover and abundance of small animal life provide the water monitor with an excellent refuge. The monitor's role in predation upon an even more endangered species, the saltwater crocodile, should be examined and adequate check on illegal deforestation (through policing, education and social forestry) implemented.

2. West Bengal has likewise protected a large area of the Sunderbans mangrove in the Project Tiger Reserve. There exists here greater faunal diversity than at Bhitar Kanika. Human activity and pressure in the area has reduced both the crocodile and water monitor to remnants of their former abundance. A survey study of the recuperation rate of these two vital predator/scavenger components of the mangrove community should be made. Adjacent areas in Bangladesh are being protected, and studied from a conservation standpoint.

3. Andaman and Nicobar Islands - The species is apparently distributed throughout the group, including most islands close offshore of the main group. These islands are characterized by dense forests of several categories with numerous mangrove-bordered creeks and bays. The water monitor is noticeably more common and less wary the further one gets away from the main settlements. We observed wary juveniles but no adults in the vicinity of Bamboo Flat (across the bay from the capital town of Port Blair), whereas we saw several adults close to the jetty and settlements around Aerial Bay in North Andaman. The Interview Island monitors are noticably heavier and larger than those seen on other parts of the Islands and certainly more vulnerable to attack by dogs (many were caught in our presence). It appears that the monitor populations of the Jarawa Reserve (a 450 sq. km. area of the western half of Middle and part of South Andaman inhabited by Jarawa negritos and off-limits to everyone else), and parts of Little Andaman and the southern islands of the Nicobars in particular are still intact and close to original in composition.

The recent placing of all monitor lizards on Schedule 1 of the Wildlife Protection Act by the Government of India will afford this "dragon" badly needed protection. As usual, proof of this law lies in its implementation. In the Andamans, nothing short of banning hunting dogs will prevent the settlers from using the monitor as a meat and fat source. In June 1978, thirty monitors killed for skin and fat were observed in North Andaman by a visiting zoologist (Choudhury, pers. comm.).

4. Sri Lanka - It was with wonder that we encountered the water monitors of Sri Lanka. They are abundant and commonly seen scavenging in garbage or swimming in streams, close to people washing clothes or bathing.

During our crocodile survey throughout the Island in September - November 1977, we made notes on the distribution of the water monitor and have compared these with the available scientific literature to formulate the following rough distribution.

1. Colombo to Hambantota (coastal south and southwestern Sri Lanka) - common.
2. Yala to Pottuvil (coastal southeastern Sri Lanka) - absent.
3. Pottuvil to Trincomalee (eastern coast) - uncommon, confined to suitable areas.
4. Trincomalee to Jaffna and to Puttalam (both coastlines of Northern Province) - apparently absent.

Fig. 2. *V. salvator* on Interview Islands in the Andamans.

5. Puttalam to Colombo (coastline of Northwestern Province) - uncommon; increasingly common toward Colombo.
6. Inland - fairly common at Polannaruwa; prior to recent drought commonly seen in Anuradhapura; seen along Mahaweli Ganga in Kandy; uncommon at Kurunegla, Kegalla and Ratnapura.

The water monitor is rarely killed in Sri Lanka. Although many people, particularly the Tamils, eat the common monitor (*Varanus bengalensis*), water monitor meat is considered poisonous and its saliva and tongue venomous. This has allowed the water monitor to thrive and grow to great proportions (2.5 m in length and 18 kgs. in weight for a large male).

CURRENT LITERATURE

The Current Literature section was not received in time for inclusion in this issue. The next issue will carry an extra group of titles.

REGIONAL SOCIETY NEWS

ST. LOUIS HERPETOLOGICAL SOCIETY

The St. Louis Herpetological Society, founded in 1974, is a group of amateur and professional herpetologists dedicated to conservation and education in all areas of herpetology. To attain this goal, the Society has published a booklet on reptile and amphibian care (to be revised this summer) and a checklist of Missouri reptiles and amphibians; it has printed a bumper sticker which asks protection for reptiles and amphibians and a poster entitled "Please Don't Kill That Snake." The SLHS also prints the JOURNAL, a publication which presents articles by its members, articles from other publications, and a variety of information of interest to herpetologists. The society also maintains a publication exchange program with approximately 25 different herpetological societies as an excellent additional source of information.

The SLHS sponsors displays at the local Museum of Science and Natural History and funds, in part, the tuatara breeding project at the St. Louis Zoo Herpetarium. It also contributes to organizations involved in various aspects of conservation, such as the Missouri Prairie Foundation. The society maintains communication with the St. Louis Zoo, the Museum of Science and Natural History, the local universities and colleges, and local humane and animal protection organizations for referrals of problems and information. The SLHS participates in regional and area symposiums, conferences and fairs, displaying and providing information and literature to the public. The society also has a speaker bureau which is available for educational presentations to groups of all ages. The SLHS has spoken to Scout groups, adult church groups and at summer library programs, to name a few.

The SLHS actively investigates and voices its disapproval of inhumane, anti-ecological, and anti-conservational practices, such as magazine advertisements which depict animal mistreatment, rattlesnake hunts, violations of the Endangered Species Act, improper care procedures at local pet shops, etc.

The SLHS membership is open to all interested persons. The society has members throughout the U.S. and in Canada and Europe. Annual dues are: Individual -$7.00; Family - $10.00; Institutional and Overseas - $15.00. The JOURNAL is published five times per year and is free with membership. For more information contact the society at P.O. Box 9216, St. Louis, MO 63117. ●

ESHL MEETING

October 1980 meeting of the Eastern Seaboard Herpetological League.
Sponsored by the Philadelphia Herpetological Society

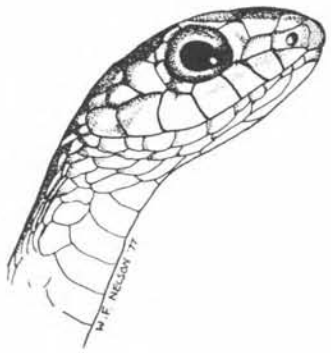
DATE: Saturday, October 25, 1980
TIME: Noon to about 6:00 PM
PLACE: Philadelphia Zoological Gardens
34th and Girard Avenue
Education and Administration Bldg.
Philadelphia, PA

NOTE: All members of ESHL constituent organizations are invited to attend this meeting. There is no registration fee. ●

WISCONSIN HERPETOLOGICAL SOCIETY

The Wisconsin Herpetological Society is a non-profit organization which was formed to encourage conservation of amphibians and reptiles, to promote the accumulation and dissemination of knowledge concerning amphibians and reptiles, and to promote cooperation and understanding among amateur and professional herpetologists and other institutions working to further knowledge and conservation.

Regular meetings are held on the third Wednesday of the odd months at the Milwaukee Public Museum. Membership is open to anyone with an interest in reptiles and amphibians. As a member you receive the bi-monthly newsletter and may attend regular and special meetings.

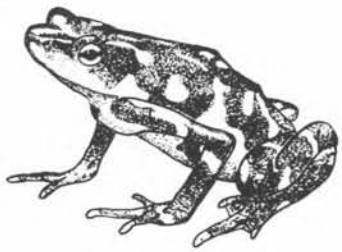


For membership information write: Membership WHS, Jeff Riedi, 8823 W. Becher St., West Allis, Wis. 53227

society for the study of amphibians and reptiles

The Society for the Study of Amphibians and Reptiles is a non-profit, international organization established to advance the study of amphibians and reptiles. Although begun in 1958 as a regional society, the SSAR has rapidly gained a world-wide membership. Today it is recognized as having the most diverse society-sponsored program of services and publications for students of herpetology. Membership is open to all persons interested in learning about amphibians and reptiles.

activities



An annual meeting is held each summer on a university campus or at a biological station in the United States. The Society especially wishes to attract students to its meetings by providing inexpensive and informal facilities. In addition to the papers given by members at these meetings, symposia or other invited speakers are usually planned which allow for detailed discussions of important areas of contemporary study. Workshops for regional society representatives have been organized for the purpose of exploring common problems and sharing new ideas. Live animal, photographic, art, and other exhibits are organized, as well as field trips.

The Society makes a concerted effort to involve a diverse segment of its membership in Committee activities designed to further our knowledge of amphibians and reptiles and manage the affairs of the Society. Committees include: Publications, Nominating, Student Prize, Systematic Resources, Common and Scientific Names, Current Literature, Regional Society Liaison, Conservation, Public Affairs, Editorial, Translations, and Annual Meeting.

publications

SSAR sponsors one of the most diversified series of publications of any scientific society. Each series is described on the reverse of this page. Back issues of most publications are available; a detailed price-list can be obtained simply by checking the appropriate box on the membership application.

membership privileges

All persons with an interest in amphibians and reptiles are welcome to become members of SSAR. Members vote on society matters, attend meetings, and participate in other Society activities. Each year members receive the following publications: Journal of Herpetology (4 issues, totaling about 400 pages), Facsimile Reprints in Herpetology (3-4 issues, about 200 pages), Herpetological Circulars (1-2 issues, about 50 pages), and Herpetological Review (4 issues, about 130 pages).

In addition, SSAR members receive a substantial discount on all book-length facsimile reprints issued during the year. Members may also place standing orders for accounts in the SSAR Catalogue of American Amphibians and Reptiles. Those persons electing the higher membership categories (Sustaining and Contributing members) receive the same publications and services, but provide additional financial support which allows the Society to expand and improve its programs more rapidly than would otherwise be possible.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

Joint Annual Meeting SSAR/HL
University of Wisconsin-Milwaukee
Milwaukee, Wisconsin
6-10 August 1980

MEETING SITE

Registration, presentation of papers, symposia and special meetings will be on the campus of the University of Wisconsin-Milwaukee. Meeting schedules will be based on Central Daylight Savings Time.

REGISTRATION

Pre-registration at reduced fees can be made until 20 June. Forms will be mailed to SSAR and HL members. Regular registration will be 6 August in the lobby of UW-M's Sandburg Towers Dormitory. Beginning 7 August registration will be in the Student Union.

FEES

Pre-registration (until 20 June)
Regular $17.50
Student $10.00

Registration
Regular $20.00
Student $15.00

TRANSPORTATION

Airline reservations should be made to Milwaukee International Airport (Mitchell Field). Milwaukee is a port of entry for the U.S. Foreign members who plan to attend may find it more convenient to pass through customs there than in Chicago. The airport is ten miles from the UW-M campus. Special transportation will be provided on 6 and 7 August (call 963-4825) and ask for SSAR/HL information desk. For drivers, Milwaukee may be reached via I-94 (see map). Parking is available at the dormitory (residents $2/day) and Student Union (pay).

ACCOMMODATIONS

On campus, rooms at Sandburg Towers will be available at the following daily rates:

Single $10.00
Double $8.00

Linen, towels and maid service are provided. Bathroom facilities will be shared between adjacent rooms. Laundry facilities are available, but there are no refrigerator or cooking facilities. Sandburg Towers has a Pizza Hut restaurant and general store-deli. Dormitory rooms will be available from 1300 h, 5 and 6 August. Please send room reservations by 20 June to guarantee space. If you reserve space and your plans change, please notify UW-M Sandburg Towers (963-4068), for refund of deposit, before 30 July to cancel your reservations. The nearest hotel and motel accommodations are about 3 miles from campus. A list of area hotels and motels is available from SSAR/HL Information Center, Milwaukee Public Museum, 800 W. Wells, Milwaukee, Wisconsin 53233 (414-278-2734).

ACTIVITIES

Depending upon interest, several field trips and other excursions may be available. These include visits to Mitchell Park Conservatory, Boerner Botanical Gardens, Schlitz Audubon Center, breweries, etc. Individuals participating in organized field trips will need to obtain collecting permits if they desire to collect frogs or turtles. They may apply to:

Scientific Collecting Permits
c/o Jim McNelly
Wisconsin Dept. of Natural Resources
Box 13248
Milwaukee, Wisconsin 53213

A narrative proposal is required! Other herps may be taken without permits unless they are listed as endangered or threatened. Researchers wishing permits for endangered or threatened species should send proposals to Jim Hale, Office of Endangered Species, Box 7921, Madison, Wisconsin 53707.

SYMPOSIA

Three symposia are planned. The arrangements for and contributions to these symposia are being handled by the symposia convenors. If you wish to participate in a symposium or would like further information, contact:

Bern W. Tryon, Chairman
SSAR Symposium on the Reproductive Biology and Conservation of Crocodilians
Dept. of Herpetology
Fort Worth Zoological Park
Fort Worth, Texas 76110

John C. Murphy, Chairman
4th Annual Regional Herpetological Societies Conference - Endangered Herptile Biology
201 Peerless Drive
Plainfield, Illinois 60544

Richard Seigel, Chairman
Fitchian Herpetology: The Descriptive Approach: A Symposium in Honor of Henry S. Fitch
Museum of Natural History
University of Kansas
Lawrence, Kansas 66045

For additional information, please call or contact:

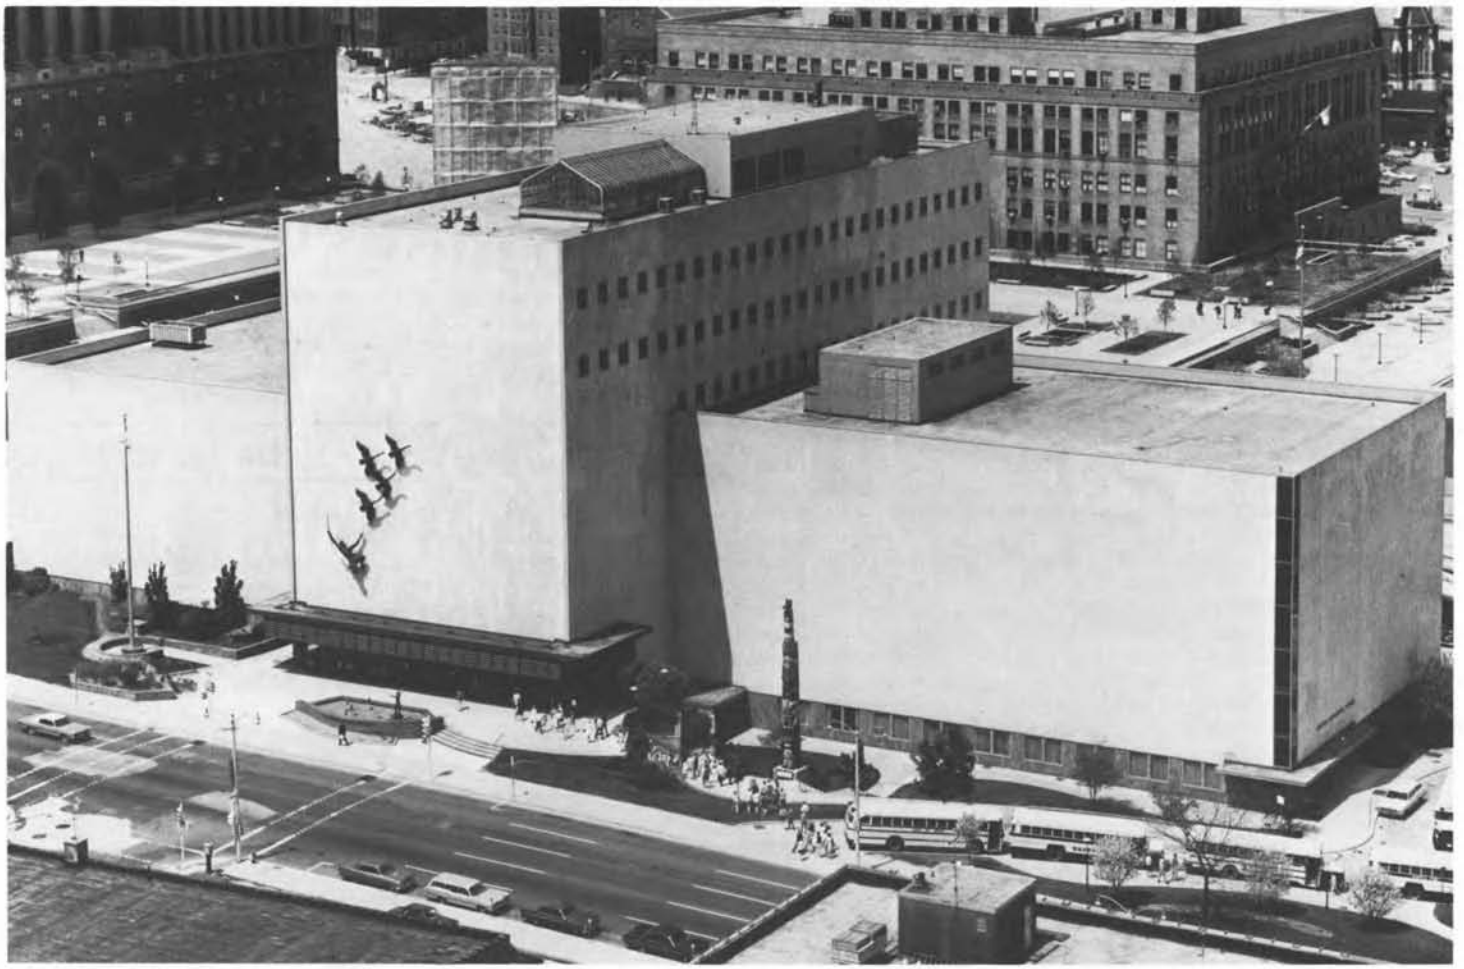
SSAR BUSINESS

REGIONAL SOCIETIES CONFERENCE

The 4th Annual Regional Herpetological Societies Conference will be held in conjunction with the SSAR/HL meeting in Milwaukee, on the University of Wisconsin campus, 10 August 1980. The meeting will be a symposium on the "Current Research and Status of Endangered North American Herptiles." Time (Tentative) 10 AM to 4:30 PM. There is no registration fee; all are welcome. ●



SECRETARY'S NOTE TO MEMBERSHIP

On 17 March, I regretfully resigned as SSAR Secretary. Joseph T. Collins agreed to serve as interim secretary and was appointed by President Bob Webb. This decision was prompted by overwhelming, and I might say unforeseen, commitments within the Association of Systematics Collections. Attempting to discharge the responsibilities of both positions has proven detrimental to both.

I value my relationship with SSAR highly, and I deeply regret having to take this action in the middle of my term, and understand that the decision will cause a number of problems in and of itself. However, I believe that in the long-run it is the right decision to make if the Society is to have more than just a figure-head in this critical position. I hope I may be of future service to SSAR, time permitting.

STEPHEN R. EDWARDS
Executive Director, ASC ●

HERPETOLOGY IN MILWAUKEE

The University of Wisconsin-Milwaukee is one of the country's major urban universities, offering the resources of a large university as well as Wisconsin's major metropolitan area to its students, including doctoral and pre-college programs, liberal arts and professional schools, sophisticated research programs and outreach activities. UWM was formed in 1956 by the merger of Wisconsin State College, Milwaukee, and the University of Wisconsin Extension Center in Milwaukee. The University traces its origins, however, to 1885 and the opening of Milwaukee State Normal School, which became Milwaukee State Teachers College in 1927, then Wisconsin State College, Milwaukee, in 1951.

The University is part of the University of Wisconsin System, which includes 13 universities, 14 two-year campuses, and the statewide UW-Extension. As the urban campus of the UW System, UWM is oriented to serve the needs of a metropolitan area, as well as to achieve a leading national and international role in selected areas of research and study. The schools and colleges at UWM include the School of Allied Health Professions, School of Architecture and Urban Planning, School of Business Administration, School of Education, College of Engineering and Applied Science, School of Fine Arts, Graduate School, College of Letters and Science, School of Library Science, School of Nursing, and School of Social Welfare. UWM offers 60 baccalaureate majors, 43 master's programs, and 15 doctoral programs. Another unit, the Division of Urban Outreach, jointly sponsored by UWM and UW-Extension, extends the instructional, research, and public service of UWM and Extension to persons not traditionally involved in campus-based learning.

The University serves more than 24,000 students on its 90-acre campus, located in a handsome residential neighborhood near Lake Michigan, and in fiscal 1978, was among the top 100 public doctorate-granting institutions in the nation in research and development expenditures.

The University of Wisconsin-Milwaukee provides facilities for herpetological research in the Dept. of Zoology and the UWM Field Station. The station has available over 1000 acres of preserve located 30 miles north of Milwaukee and includes S.E. Wisconsin's largest protected tamarack-cedar bog. Research at the station has included distribution and population studies of Wisconsin turtles, salamanders and frogs. The facilities are available for use by any investigator through arrangements with the Director. Cooperative arrangements with the other 27 campuses of University of Wisconsin Systems provide additional opportunities for research throughout the state.

Three faculty members are directly involved in herpetological research. Dr. James R. Coggins, an ecological parasitologist, is involved in the systematics of the parasite genus *Phyllodistomum* (found as a bladder parasite of some salamanders) and is currently supervising a parasitological survey of Wisconsin amphibians. Sampling so far has included all native Wisconsin salamanders and many frogs. Dr. Albert Williams continues a comparative study of the reproductive system of salamanders. Specifically investigated is the sperm transport system in the male glandular production of spermatophores, and the effect of cloacal gland secretions on sperm maturation and activity. Richard Sajdak's graduate research has included a population study of *Necturus* utilizing radiotracking techniques and distributional surveys of Wisconsin amphibians. Dr. John E. Minnich has been conducting studies on several aspects of water, energy, electrolyte and nitrogen metabolism in vertebrates, especially reptiles. His approach has been primarily ecophysiological, but has also included endocrinological and even cellular studies. Recent herpetological studies (many in collaboration with former graduate students) include the following water and electrolyte fluxes in free-living desert and gopher tortoises, endocrine control of sodium fluxes in mudpuppy salamanders and effects of calcitonin on kidney and salt gland function in desert iguanas.

Currently Dr. Minnich is preparing to investigate seasonal variations in water and energy budgets of free-living gopher tortoises in Florida, using the doubly-labeled water method.

Three graduate students are currently studying under Dr. Minnich's supervision, two in herpetological areas. Scott Stegbauer recently completed his M.S. dissertation on effects of osmoregulatory hormones on the ultrastructure of the lizard cloaca. He and Dr. Minnich are also conducting similiar studies on the nasal salt gland of lizards. Drew Hildebrandt is conducting studies on the effects of hydration state, salinity and dietary nitrogen intake on renal clearance of ammonia, urea and urate in several species of turtles (painted turtle, diamondback terrapin, box turtle and desert tortoise).

The collections of the Milwaukee Public Museum trace their origins to the efforts of local individual citizens. In the 1850's Peter Englemann assembled natural hisotry collections at the German English Academy where he was a schoolmaster. Originally these collections were used as adjuncts to classroom study. The collections continued to grow, and in 1857 Englemann helped form *Der Naturhistorische Verein von Wisconsin* (the Natural History Society of Wisconsin) which assumed curatorial responsibility for the collections. This society became concerned with making collections available to the general public and offered them to the City of Milwaukee with the provision that it establish and maintain a free museum of natural history. the state legislature passed enabling legislation in 1882, and in 1884 the Milwaukee Public Museum opened its doors to the public.

The new Museum grew rapidly. During its first fourteen years it was housed in a section of the Industrial Exposition Building. Additions to the collections resulted in the city providing more space by opening a joint library-museum building in 1898 with 47,000 square feet allotted to the Museum. In 1905 the museum acquired an additional dimension when "history" was added to its "natural history" designation. Continued collection growth resulted in temporary storage space in various adjoining buildings and by the mid 1950's mandated new quarters for the Museum.

These new quarters were provided in 1963 with completion in downtown Milwaukee of the present seven story building which has special air filtration and conditioning systems to minimize specimen deterioration. The ground floor contains the Education Division, a small animal zoo, trading post, classrooms and the cafeteria. The next three floors together with a small ground floor exhibit area provide a total of 165,000 square feet of exhibit space, and the last three floors have a total of 120,000 square feet for collections, laboratories, and offices. Approximately 33,300 square feet in the basement are used for storage of collections not on display.

With the continued growth of the museum collections and the simultaneous growth of the Milwaukee metropolitan area the museum began to serve not only the educational, cultural, and scientific needs of citizens of the city of Milwaukee but also those of nearby communities. This increased constituency was recognized in 1977 when the County of Milwaukee purchased the Museum from the city and assumed responsibility for its operation. The Museum is one of the half dozen largest and best known natural and human history museums in the United States. Because of its size and the scope and quality of its programs it serves not only residents of Milwaukee County but also those of virtually the entire state of Wisconsin and much of the upper Midwest.

Since 1971 the museum has been reorganized under the leadership of the Director, Dr. Kenneth Starr. Systematic collections are now housed in four sections and emphasize Wisconsin, central United States, Latin America, and other areas of research interest to past and present curators.

Vertebrate Zoology houses MPM's largest natural history collections, approximately 1,250,000 specimens, some dating from the 1840's. The herpetological collection has 18,750 catalogued specimens, and geographic regions featured include Wisconsin, central U.S., Belize, and Amazonian Peru. The herpetological staff includes Dr. Max A. Nickerson, Curator and Robert W. Henderson. Mr. Henderson's current research includes convergent behavior in attenuate-snouted tree snakes, the ecology of milk snakes, and a multi-faceted study of vine snake behavior, ecology and morphology in collaboration with Mary H. Binder. Laboratory studies are being conducted along with field work on *Uromacer* in the Dominican Republic. Nickerson is continuing ecological studies of cottonmouths, northern water snakes, and map turtles. He is also assisting Dr. J. M. Fujimoto and S. C. Roerig with studies of the hepatic enzyme system for reducing naloxone to 6 α and 6 B-naloxol in vertebrates and continuing some hemoglobin studies with Dr. F. Taketa at the Medical College of Wisconsin. Other herpetologically involved staff include Dr. Teresa Noeske investigating the effect of temperature regimes on *Anolis* reproduction and fattening and Dr. Merlin Tuttle studying Neotropical bat interactions with anurans in Barro Colorado.

Milwaukee is justifiably proud of its large modern zoo. The *Milwaukee County Zoo's* Reptile and Aquarium Building opened in 1968 under the supervision of Dave Zucconi, now Director of the Tulsa Zoo. The building displays over 100 species of reptiles and amphibians with a number of additional species not on display. The collection is maintained by two keepers under the direction of Sherman Ketcham, Curator. Keepers Cliff Van Beck and Richard Sajdak are continuing graduate studies at UWM.

Staff are involved in research projects with many institutions including the Medical College of Wisconsin, University of Illinois-Urbana and the Milwaukee Public Museum. The Zoo cooperates with the Milwaukee Public Schools, Wisconsin Department of Natural Resources and other groups in providing animals and displays for educational purposes.

Recently some reptilian cages have been renovated into more naturalistic displays using gunite and other materials. The new cage designs afford an increased number of species per display and an improvement in animal husbandry. Plans are under way to remodel the remaining cages. Future plans include better environmental controls and increased display area in the building.

Under the leadership of Milwaukee's new zoo director, Dr. Gilbert K. Boese, the reptile section anticipates increased emphasis on research and reproduction. A special commitment will promote the husbandry and propagation of endangered species.

Legislative Alert

20 February 1980
The Honorable Fred Richmond
The House of Representatives
U. S. Congress
Longworth House Office Building
Washington, D. C. 20515

Dear Mr. Richmond:

The Society for the Study of Amphibians and Reptiles (SSAR) is an international organization with over 1,800 members. It expresses concern in regard to House Bill H. R. 4805, the "Research Modernization Act."

The bill seems to confer a blanket condemnation on the use of all captive live animals, regardless of the purpose of the research. This could then affect herpetological research involving behavioral studies, breeding experiments, etc. I don't believe the bill was intended to deal with the above, so perhaps a definition of the types of research to which this bill pertains should be outlined. The definition of animal also needs clarification. Does it include *Drosphila* and bacteria as well as mammals?

It would be dangerous to consider that the results of experiments demonstrated by models would be the same as those results on living systems. Therefore, predictions derived from experimentation with models could not be certainties unless tested on living systems.

Section 6b of the act concerning duplication of research is vague. Repeatability is a basic tenet of the scientific method for validating conclusions drawn from an experiment. Thus, duplication of experiments would seem a very proper activity of scientists. This section could preclude funding for any study which would use live animals to test conclusions derived from models.

Ordering agencies to direct 30-50% of all research appropriations to developing alternative research methods (Section 10) represents a tremendous and sudden shift in research direction. Perhaps it would be well advised to enter this program cautiously and gradually, if at all.

In summary, research models have their place in certain types of research, but not in others. To suddenly plunge into extensive model use by financially obligating research-

ers to participate in such a program may lessen research productivity and cast doubt on the practical application of experimental results. If research involving models is highly favored, it is feared that research which cannot involve the use of models might receive secondary consideration in funding.

Sincerely,

Hugh Quinn, Chairperson
SSAR Legislative Alert Committee ●

ALDRIN PERSISTS IN YELLOW MUD TURTLE

On the evening of 8 June 1974, a female yellow mud turtle (*Kinosternon flavescens*) (weight 110.1 g) in a state of ataxia (swimming on its side in circles) was collected in a flooded rice field near Chocolate Bayou, Brazoria County, Texas. The whole carcass was frozen and stored until analysis at Patuxent Wildl. Res. Cntr. in October 1977. Extraction, sample cleanup, and separation of organochlorine pesticides and polychlorinated biphenyls (PCB's) were described by Prouty, *et al.* (1977). The turtle contained 4 ppm aldrin, 47 ppm dieldrin, 1.3 ppm endrin, and 0.3 ppm toxaphene (all on a wet weight basis). No PCB residues were detected. The turtle was apparently suffering from insecticide poisoning. The rice field in which it was found had been planted with seed treated with aldrin at 113g/45kg (4 oz/100 lb.) at 45.4kg/0.4 ha (100 lb/A) on 9 May and had received an application of toxaphene on 1 June.

Aldrin is metabolized rapidly to dieldrin in warm blooded animals (Brann, *et al.*, 1956; Flickinger and King, 1972) and in freshwater fish (Ludke, *et al.*, 1971). No aldrin was found in 3 species of moribund snakes collected in rice fields (Flickinger and King, 1972) 2 weeks after the fields were planted with aldrin-treated seed in 1970. However, dieldrin residues ranged from 0.1 to 5.7 ppm in whole bodies of

Amphibians and Reptiles of the Carolinas and Virginia

by Bernard S. Martof,
William M. Palmer,
Joseph R. Bailey, and
Julian R. Harrison III
Photographs by Jack Dermid

The first illustrated guide to the amphibians and reptiles of the Carolinas and Virginia. Here—in stunning color photographs and with up-to-date accounts—are the region's 159 species of frogs, snakes, turtles, salamanders, lizards, and alligator. Range maps indicate where each species is found.

Each species account is illustrated and includes comments on distinguishing features, distribution, habitat, and life history. The text describes the geography, vegetation, and climate of the entire area and outlines its herpetofaunal history. A listing of endangered species, an index, a glossary, and a list of useful references also are included.

the snakes. Epoxidation of aldrin to dieldrin may occur rather slowly in turtles because of their low metabolic rate. A whole composite of 2 red-eared turtles (*Pseudemys scripta elegans*) that were collected alive in rice fields contained 4 times more aldrin (4.8 ppm) than dieldrin (Flickinger and King, 1972) 14 weeks after the fields were planted with aldrin-treated seed in 1970. Female yellow mud turtles were known to wander more than most turtles (Mahmoud, 1969). But, the yellow mud turtle and the red-eared turtles could have been exposed to aldrin in other rice fields more recently planted with treated seed.

ACKNOWLEDGEMENTS

We thank Harold E. Rawlings, rice grower, Iowa Colony, for use of his thorough records of rice planting dates for Brazoria County.

AN ALBINO EASTERN BOX TURTLE, *TERRAPENE C. CAROLINA*, FROM NORTH CAROLINA

Hensley (1959) recorded albinism in the widespread and common box turtles, genus *Terrapene*, on the basis of a partially albinistic specimen of the eastern box turtle, *T. c. carolina*, from Ohio. I found only one other record of this anomaly in this genus, in an individual of the Gulf Coast box turtle, *T. c. major*, which showed partial cephalic albinism (Anonymous, 1968). I here report on the first case of complete albinism in *T. c. carolina*, in a North Carolina specimen.

The turtle, a juvenile, was found by an unidentified person on a cement carport in Cape Carteret, Carteret County in June 1976. The specimen was kept captive for about one year. It fed readily during early captivity, but it did not feed later on and died of unknown causes on 14 June 1977. Carapace length, width and height (in mm), respectively, at death were 42.7, 34.9 and 15.7; weight was 12.0 g.

The over-all color of the turtle appeared light yellow. Closer examination, however, revealed that the color of the carapace and of the head was actually a tightly mottled light yellow and white. Portions of the scales of the limbs were light yellow, and other portions were white. The undersides of the marginal scutes, the underside of the cervical scute, and the edge of the plastron were predominantly yellow, but with patches of white. The rest of the plastron was white, but with scattered small light yellow spots. The plantar surfaces of the feet were white. The iris of the eye was pink. All parts of the turtle in preservative appear white (Fig. 1). Conant (1975) presents color plates of a normally-colored live juvenile of this subspecies. My specimen is also unusual in that it has 13 marginal scutes per side instead of the usual 12. Behavior of the turtle when captured appeared to be normal.

I thank Fred C. Rohde, the fourth person to own the turtle, for passing the specimen on to me, for data on the turtle, and for several 35 mm color transparencies of it. The specimen is now in the collection of the Carnegie Museum (CM 70253).

A HIBERNATING EASTERN HOGNOSE SNAKE, *HETERODON PLATYRHINOS*

Published reports of hibernating snakes are numerous (see original data and literature review in Parker and Brown, 1973), but for the hognose snakes, *Heterodon*, detail is available only for the eastern hognose, *H. platyrhinos*. Neill (1948) reported that in Richmond county, Georgia, *H. platyrhinos* hibernates singly, beneath rocks, stumps, or rubbish piles, in burrows in hard red clay soil, and beneath slabs of tin, and that it is semi-dormant when disclosed. Anderson (1965) stated that it usually hibernates in rodent burrows in open fields and that it is conspicuously absent from the limestone ledge hibernacula that most snakes select. He noted (in Platt, 1969) that a specimen emerged from a thirteen-lined ground squirrel (*Spermophilus tridecemlineatus*) burrow on 8 April, and that a torpid *H. platyrhinos* was found in a mole tunnel at a depth of approximately three feet in mid-November. Platt (1969) stated that where the soil is suitable, the species probably hibernates in burrows which it has dug, and Collins (1974) reported that it burrows deep into loose soil or sand to overwinter. Platt (1969) noted that *H. platyrhinos* has not been found in hibernation dens with other species of snakes. Lee (1968), however, recorded one eastern hognose in hibernation with numerous individuals each of four species of snakes and seven species of amphibians, in and above a small spring in Baltimore County, Maryland. In view of the paucity of information available on hibernation in this otherwise well-known snake, the following observations, made in Pomona, Atlantic County, New Jersey, are of interest. Temperatures were taken with a Wesco rapid register thermometer.

At 2:45 P.M. on 16 October 1977, I observed an adult *H. platyrhinos* on the wide shoulder of a dirt road. Its head and neck were buried in a sand substrate, and the body extended and

the last one-third looped upon itself. No movement was noted during several minutes of observation. Suspecting that the snake was in the process of burying for hibernation, I did not disturb it. Not wishing to attract the attention of other persons nearby, I then left the area and returned periodically. At 3:45 P.M., the snake was about one-half buried; at 5:00 P.M. only the last 10 cm were visible; and at 5:40 P.M. the specimen was no longer visible on the ground nor in the open hole and was presumably buried. No movement of the exposed portion of the snake was ever noted. The weather was sunny and clear, with a moderate SW wind. Soil temperature near the digging snake (4:00 P.M., at about 2 cm depth) was 16.5°C, and air temperature (at ground level, in shade, and out of wind) was 18.5°C. The height of the hole left by the snake was 1.7 cm and the width 1.5 cm.

Much of the Pomona, New Jersey, region is coverd by young mature forest of black oak, *Quercus velutina*; white oak, *Q. alba;* shortleaf pine, *Pinus echinata;* and pitch pine, *P. rigida*, with a pronounced understory of blueberry, *Vaccinium* spp., and huckleberry, *Gaylussacia* spp. This association bordered the road shoulder 1 m from the digging snake, and for much of each day shaded the spot chosen by the snake. The shoulder itself was almost devoid of vegetation except for a few sapling sassafras, *Sassafras albidum*, and scattered patches of low mosses and lichens; much of the soil was exposed or thinly covered with scattered leaves and pine needles. The soil type where the snake was found is Klej loamy sand, 0 to 3% slopes (Johnson, 1978).

On December 1977 I attempted to locate the snake. The hole was still distinct. The burrow proceeded almost straight down, but I was able to follow it for only about 10 cm; I then continued to dig particularly carefully. The sandy substrate and the almost total absence of tree roots facilitated digging. I found the snake at 12:30 P.M., buried at a depth of 58 cm in moist sand and about 15 cm off the vertical as measured from the entrance hole. The snake was coiled (not looped *sensu* Brown, *et al.*, 1974). Immediately when uncovered, it moved relatively quickly and hissed, and made strong attempts to escape while its cloacal temperature was being taken; the specimen was definitely not sluggish. I then partly re-buried the snake in a loose coil prior to recording the temperature data; it immediately began to crawl slowly around the bottom of the hole with its neck spread. Cloacal temperature was 9.2°C; sand temperature (at 2 cm depth at spot where the snake was found) was 8.5°; and air temperature (taken as before) was 11.0°C. Weather was mostly sunny with a light NW wind.

A few minutes later, while carrying the snake a short distance to my home in order to measure and weigh it, it first vigorously attempted to escape, then spread its head and neck and coiled its tail in the characteristic bluffing display. It then quickly began the death feigning display and rolled on its back, opened the mouth, extended the tongue and partially everted the cloaca and made movements to void the contents (no material was expelled). Total length of the specimen was 46.5 cm and weight was 53.6 g. The snake was scale-clipped for future identification and carefully re-buried where found. On 17 January 1979 the area was thoroughly excavated again, and to a much larger extent than previously, but I found no snake or snake remains. The air temperature at the time was 3.0°C; surface soil temperature was 0.1°C; and soil temperature at 58 cm was 3.1°C, and may represent the annual low soil temperature at this depth at this spot. The soil was again distinctly moist, but not wet.

Although I cannot be positive, I suspect that the snake burrowed along an ant tunnel. The digging snake was found near the center of a small mound 15 cm long, 11 cm wide and to 3.2 cm high, and devoid of any living and dead vegetation. No ants were noted on 16 October or 3 December, perhaps because I did not observe carefully enough, but subsequent examination of photographs of the digging snake and the entrance hole suggests that this mound was an abandoned or little-used ant mound. When the area was excavated on 17 January 1979, a number of ants were noted in some of the few tunnels found. The tunnels were ± 0.8 cm wide and extended down to a depth of at least 60 cm. Use of ant tunnels and nests by hibernating snakes has been frequently noted (see partial literature review in Parker and Brown, 1973).

Conant (1938) and Klimstra (1958) recorded *H. platyrhinos* active from April to October in Ohio and in Iowa, respectively; the same is probably true of this species in New Jersey.

Reptile HOT BLOCK

Research has shown that "coldblooded" animals absorb heat from the surface they lie on. The HOT BLOCK provides a safe, water-resistant, thin warm surface that can be placed at the bottom of an animal's cage, either on the surface or buried under a suitable substrate.

HIDING PLACES

A unique concept in providing security for a small pet. hollow half logs provide a natural HIDING PLACE in which the animal can seek shelter.

Evergreen

TERRARIUM MOSS

A natural moss, fixed and enhanced in color, so the bright natural color never fades. It is also sealed in a special Latex bath so it may be kept continously damp without loss of color or fear of deteriation.

TERRAFAUNA p.o. box 3425, Van Nuys, Ca. 91407

Mean air temperatures when the snakes were entering and leaving hibernation in Ohio ranged from 10.0-15.6°C (Conant, 1938). Air temperature data obtained from the National Oceanic and Atmospheric Administration for Pomona, New Jersey indicate that for October 1977 the average daily maximum temperature was 18.1°C, the average daily minimum 7.3°C and the monthly average 12.7°C; these temperatures are all slightly below those of a 30-year mean. For fall 1977, the first average daily temperature in the 10°C - 15°C (50's F) range occurred on 3 October and continued each day until 16 October. The first fall 1977 daily average in the 4.4°C - 9.9°C (40's F) temperature range occurred on 17 October, the first temperature below 4.4°C (in the 30's F) occurred on 11 October, and the first freezing temperature on 12 November.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Dept. of Herpetology, Fort Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, TX 76110.

OBSERVATIONS ON THE REPRODUCTION OF THE COMMON ANACONDA, *EUNECTES MURINUS*, AT THE NEW YORK ZOOLOGICAL PARK

Eunectes murinus is a semi-aquatic boid whose range extends over much of tropical South America (Peters and Orejas-Miranda, 1970). The breeding season for *E. murinus* varies throughout its range and is summarized by Fitch (1970). Additional breeding data are provided by Dixon and Soini (1977).

Information on the captive breeding of *E. murinus* is meager (Deschanel, 1978). Between 5 February 1978 and 30 November 1978 three female *E. murinus* gave birth at the New York Zoological Park (=NYZP). Observations on growth and reproductive behavior of the parents and pertinent reproductive data were recorded. Post-parturient behavior was noted and will be discussed in a later account.

A female *E. murinus* (NYZP #760033, = female #1), acquired in June 1971, measured 1.42 m in total length (= TL) and weighed 1.35 kg. Estimated age was one year. In June 1975 a 1.83 m TL, 7.7 kg male (NYZP #760034, = "the male") was acquired as a prospective mate. Age was estimated at three years. The two were placed together on 15 April 1976. Female #1 then measured 3.2 m TL and weighed 25.5 kg; the male 2.4 m TL and 11.4 kg. On 9 May 1976 they were placed in an exhibit enclosure measuring 2.45 m by 1.85 m by 1.75 m high. Substrate consisted of smooth river gravel. An oval pool 1.35 m by 1.0 m by 0.31 m deep was provided on one side. Tempered water maintained at 28°C (±2°) was continually added to the pool. Air temperature was 27°C (± 2°). A heating coil at one end of the cage provided a substrate thermal gradient of 26°C to 30°C. The exhibit was dimly illuminated by three 75 watt Duro-Test incandescent flood lights. The photoperiod was 8.5 to 9 hours per day year round.

On 11 October 1976 a second female (NYZP #760241, = female #2) was added to the group. This female, approximately 3 m TL, was born in February or March 1971 in Iquitos, Peru (Timothy Warke, pers. comm.). In March 1978 she weighed 45.64 kg at 3.8 m TL.

A third female (NYZP #770291, = female #3), 3.3 m TL and 25.54 kg in weight, was introduced on 6 April 1978. Female #3 was acquired in November 1971 at .91 m TL and was judged to be less than one year old.

Each member of the *E. murinus* group was offered food once per week. Diet items included freshly killed domestic ducks, chickens, rabbits, and laboratory rats.

On 24 May 1977 the male and female #1 were observed courting at 1500 hours and continued for at least two hours. Courtship took place within the pool. The male frequently flicked his tongue over the dorsal areas of the female as he aligned the anterior portion of his body over the same region of the female's body. The posterior portion of the male's body and tail completely encircled the female's cloacal region several times. Subsequent courtship involved both encircling and draping of the female's body by the male. Copulation was not noted. This was the first reproductive behavior noted for any of the four snakes. Since then, courtship between the male and female #2 has been observed on nine occasions between 5 April and 26 May 1978 and on 7, 23, and 26 May 1978 it terminated in copulation lasting from ½ to 2 hours. Courtship and copulation were noted between the male and female #3 on 22 May 1978. Sexual activity has only been observed in the water and usually occurred shortly after reintroduction of the previously separated male to the enclosure. Separations were from one to seven days.

Female #1 fed twice between courtship and parturition. Female #2 fed seven times and female #3 not at all.

On 17 October 1977 female #1 was radiographed and appeared to contain multiple egg masses of uniform opacity. Her weight was 30.3 kg. An additional radiograph taken 2 February 1978 disclosed numerous fully formed skeletons. Although a portion of the embryos appeared to be in the normally coiled enveloped position, others were outstretched, suggesting that they had already emerged from the embryonic membranes while still within the oviduct (see Figure 1).

By 0830 hours, 5 February 1978, female #1 had given birth to twenty-seven young. None were enveloped upon discovery and all umbilical herniae were closed. At birth they weighed 210.4-278.0 g, $\bar{x}$ = 249.2 g. Total length was 800-855 mm, $\bar{x}$ = 843.9 mm.

Female #3 had at least twenty-three young between 0830 and 0930 hours on 19 November 1978. None were enveloped but almost all had umbilici and fetal membranes attached. Twenty-two of the young weighed 191.8-230.5 g, $\bar{x}$ = 206.2 g, and measured 730-765

Figure 1. Radiograph taken 2 February 1978 revealing outstretched young within ovaduct of female #1 three days prior to parturition.

mm, $\bar{x}$ = 748 mm TL. One undeveloped egg was passed.

Parturition in female #2 occurred sometime between 1630 and 2210 hours, 30 November 1978. The litter included twenty-eight live and two dead young. One undeveloped egg was passed. When discovered, none were enveloped and all but one of the live young had shed fetal membranes and umbilici. The thirty young weighed 248.2-302.5 g, $\bar{x}$ = 265.4 g, and total lengths were 855-900 mm, $\bar{x}$ = 877.1 mm.

Females #2 and #3 generally remained in the pool during gestation, while female #1 usually was coiled directly over the substrate heating coil, an area normally avoided by all four snakes. Accelerated shedding cycles were experienced by all three females during gestation. Females #2 and #3 each shed normally six times while female #1 experienced three periods of opacity that did not terminate in ecdysis, followed by four complete shedding cycles. The resulting shed skins were abnormally thick. Presumably the shedding abnormalities experienced by female #1 were related to the dessicating effects of the heating coil. Female #1 was frequently observed breathing with her mouth partly open while in the heated area. During the twelve month period previous to gestation, females #1 and #2 each shed seven times, while female #3 shed five times.

Based on their size and the rate of growth of young *E. murinus* in the New York Zoological Park collection, the three female *E. murinus* were estimated to have reached sexual maturity in their sixth or seventh year. Although the male's early history was unknown, he was estimated to have achieved sexual maturity at five years of age.

ACKNOWLEDGEMENTS

I would like to thank the following for their contributions to this manuscript: John L. Behler, Curator of Herpetology; Peter Brazaitis, Superintendent, Department of Herpetology; Elizabeth Russo, D.V.M., Department of Medical Services; and the New York Zoological Society.

A LONGEVITY RECORD FOR *CTENOSAURA PECTINATA* (REPTILIA: IGUANIDAE)

Gibbons (1976) gives comparative longevity records for the Class Reptilia and indicates that only 18 species are reported attaining 10 years of age, of these only six attain 15 years (of which *Ctenosaura pectinata* is not listed), and of these only two species live to 20 years in captivity.

The previous published longevity record *C. pectinata* was 8 years 2.5 months (Bowler, 1975). This specimen was maintained at the Dallas Zoo; it died in March 1978 (J. B. Murphy, Personal Communication, 1978), giving it a total minimum age of 11.5 years.

The 1963 College of Idaho Field Biology Expedition collected a juvenile male *C. pectinata* on July 31, 1963 in Mazatlan, Sinaloa, Mexico. The collection site is at Latitude 23°13'N, Longitude 106°25'W and at an elevation near zero.

At the time this paper was submitted (1 April 1980), the lizard was alive and had attained a minimum age of 16 years, 9 months. The lizard grew the first 2-3 years in captivity and was estimated to be approximately 3-4 years of age on capture.

It now has a snout-vent length of 30 cm, a total length of 72 cm, and a weight of ca. 900 g.

The *C. pectinata* has been housed since August 1963 in a large glass terrarium with a sandy substrate and a UV light source. The diet of the lizard has consisted mainly of apples, small tomatoes, lettuce, and dandelion flowers, depending on seasonal availability.

The specimen apparently has a condition known as fibrous osteodystrophy, a common disorder in iguanas fed mainly lettuce and fruit (Frye 1973). The lizard has a good appetite, despite the aforementioned illness and failing vision.

ACKNOWLEDGEMENTS

We appreciate discussions with James B. Murphy (Dallas Zoo) and J. Kevin Bowler (Philadelphia Zoological Garden) concerning this record.

CAPTIVE PROPAGATION IN THE LANCEHEAD RATTLESNAKE, *CROTALUS POLYSTICTUS*

Little is known about reproduction in the lancehead rattlesnake, *Crotalus polystictus*. Klauber (1972) reported litters of 3 and 20. Armstrong and Murphy (1979) recorded litters of 10, 12, and 3 litters of 7 offspring. Two females, collected by Robert E. Humphries near Tapalpa, Jalisco, Mexico, had litters of 6 each. All litters were from wild caught gravid females.

On 21 July 1978 a pair of *C. polystictus*, captive since September 1973, produced a litter of three. This is the first report of captive propagation. This pair was maintained in a glass-fronted display measuring 60 x 40 x 55 cm. The substrate was small rocks with larger rocks stacked so that hiding spaces were available. Oak leaves and dried plants also provided cover. Freshly killed adult white mice were fed to the pair approximately every 21 days. Water was provided in a glass dish.

Courtship activity was similar to *Crotalus d. durissus* (Armstrong and Murphy 1979). Copulation was first observed on 3 August 1977. Coitus lasted 8 hours. No movement from either snake during coitus was observed. The female's cloacal region was distended during coitus and after separation. The snakes also copulated 11 August 1978, 21 days after birth of the offspring.

The adults were sprayed with chilled water (5°C) every morning from June through

August. A constant temperature of 29° C was maintained in the display but after spraying, the temperature dropped to 23° C. This always stimulated male courtship activity. The spraying period corresponded to the summer rainy season of the high plateau environment inhabited by *C. polystictus*.

The young were measured to the nearest millimeter (Quinn and Jones 1974) and weighed to the nearest .1 g. Total length of the young were 223, 210 and 207 mm ($\bar{X}$=213.3 mm). The young (n=48) reported by Armstrong and Murphy (1979) had a mean length of 214 mm. The weights of my neonates were 10.2, 10.4 and 8.8 g ($\bar{X}$=9.8 g). The neonates described by Armstrong and Murphy (1979) had a mean weight of 8.9 g. The young shed 9-11 days after birth and then fed readily on newborn mice.

ACKNOWLEDGEMENTS

I am indebted to James B. Murphy for supplying additional data and to Hugh R. Quinn and John E. Werler for reviewing this manuscript. My appreciation is also extended to the Herpetological staff of the Houston Zoological Gardens. The specimens will be deposited at University of Texas (Arlington) upon death.

NEWSNOTES

U.S. SEA TURTLE STAMPS

Strong support is needed for the IUCN Marine Turtle Specialist Group's petition to the U.S. Postal Service to create a series of sea turtle stamps. These commemorative stamps would be intended to increase public awareness of endangered sea turtles. Four species that occur in U.S. waters would be featured. Readers are urged to send letters of endorsement to Mr. William Bolger, Postmaster General, Washington, D.C. 20260. ●

NC HERPETOLOGICAL SOCIETY RECEIVES CONTRACT TO STUDY *HYLA ANDERSONI*

The North Carolina Herpetological Society has signed a $3,000 contract with the US Fish and Wildlife Service to study the distribution of *Hyla andersoni* in North Carolina. The research will be conducted under the guidance of society advisor Ray Ashton, North Carolina State Museum. The three primary purposes of the study are to check the 43 historic site records, (10 years or older). These sites will be visited to determine if the habitat will still support pine barrens treefrogs and, hopefully, to locate frogs at these locations; secondly, new sites will be located and habitat type and size will be determined;

HERPETOLOGICAL

TERRAFAUNA 5148 Minturn Ave., Lakewood, Cal. 90712

and data will be shared with a similar project being headed up by Larry Wilson at Clemson University.

Several teams will be mobilized to cover various assigned regions of the coastal plain on nights when *H. andersoni* should be active. Each team will collect voucher specimens, calling population data, habitat information, and exact localities of each call site.

The NC Herp Society is involved in a similar study on the distribution of *Clemmys muhlenburgi* in the western part of North Carolina. This study is being headed by Ray Johnson of Durham, NC. The conservation committee of the society, headed by John Wiley and Wilson Laney of NC State University, is collecting information on Laurinburg Pond, a site where numerous coastal plains herps breed. This data is being turned over to the NC Heritage Program and the Nature Conservancy with the hope that these institutions can save the area. ●

MALDIVIAN TURTLE STAMPS

The Republic of Maldives has issued a series of postage stamps depicting seven species of sea turtles found in their waters. Cost per set is Rs 14.93; this includes the *Chelonia mydas* souvenir sheet. The special first-day cover envelope costs Rs 1.00 (exchange rate: U.S. $1.00 = M. Rs 3.93). Individual stamps are also available. Order from Postmaster, General Post Office, Malé, Republic of Maldives. ●

TURTLE CATALOG ACCOUNT VOLUNTEERS

Attempts to contact four individuals who have been assigned turtle accounts to prepare for the *Catalogue of American Amphibians and Reptiles* have failed:

Robert Feuer (*Chelydra generic, Chelydra serpentina*),
Keith Hawthorne (*Caretta generic, Caretta caretta*),
Douglas Reagon (*Terrapene carolina*),
Roger Sanderson (*Graptemys barbouri*).

Correspondence to their last known address has gone unanswered. If any of the above individuals are still interested in preparing these delinquent accounts they should immediately contact the Testudines Section Editor, Dr. Carl H. Ernst, Department of Biology, George Mason University, Farifax, Virginia 22030! If the editor does not hear from them by September 1st, the accounts will be forfeited and reassigned. ●

MARINE TURTLE AGING RESEARCH

HERPETOLOGICAL ASSOCIATION OF AFRICA

The Herpetological Association of Africa is now 15 years old, but can trace its genealogy back a further 7 years to the birth of its parent Society - The Herpetological Association of Rhodesia. During this long period the Association's Journal has been, and remains, the only publication dealing specifically with African herpetology.

The Journal (3-4 issues a year) is well illustrated, and caters for both the professional and amateur herpetologist. Membership is open to all interested persons (R4.00 or $6.00 per annum) and details can be obtained from the Secretary, Dr. W.R. Branch, Port Elizabeth Museum, Box 13147, Humewood 6013, Port Elizabeth, South Africa. ●

FORCE FEEDING INFO DESIRED

Larry Cartmill (785 Mohawk Drive, Barboursville, W. Va. 25504) reports good success raising juvenile *Elaphe obsoleta rossalleni* and *Crotalus horridus* by force-feeding pink mice and pieces of adult mice. He would like to correspond with others having similar experiences. ●

DICEPHALIC *KINOSTERNON*

On July 1, 1979 a Yellow Mud Turtle (*Kinosternon flavescens*) which had recently been collected near Levelland, Texas (Hockley County) laid three eggs. The eggs were maintained in a medium of Cypress Bark Mulch at room temperature and hatched on August 8, 1979. To our surprise, we found one of the youngsters to be dicephalic.

A CLARIFICATION

Please add the following, which was omitted from my article on page 115 of Herp Review 10(4): after male (483 mm total length) *collected 31 March 1971, 1.7 km SW Switzerland, Jasper Co., S.C.* There has been some question as to whether the female was gravid when collected. With the addition of the male's collecting data this should clear up the matter.

DENNIS W. HERMAN
Sr. Keeper, Herpetology
Atlanta Zoo ●

A CONVENIENT KILLING AGENT FOR AMPHIBIANS

A collecting trip that involves hiking into inaccessible areas or a business or pleasure trip combined with a little collecting often demand that collecting equipment be kept to a minimum. Aqueous killing agents demand more weight, another jar, etc.

Medication for toothaches that come in a gel form and packaged in a neat, flexible squeeze tube alleviate these problems. These gels (e.g., Ora-jel, Commerce Drug Company), which are available in any drug store, contain benzocaine. A quite small amount smeared on the top of the head of an amphibian will kill it in a completely relaxed condition within a few minutes. The technique was not tried on any reptile, but it should work, at least on small species.

An additional advantage is that the compounds will pass through international customs without any hassle from the officials.

RONALD ALTIG
Department of Biological Sciences
Mississippi State University
Mississippi State, Mississippi 39762 ●

SYMPOSIUM REPORT

The Fourth International Symposium on African Amphibians met in Florence, Italy, December 10-15, 1979. There were 24 participants from 10 countries. The meeting was organized by Dr. Jean-Jacques Morere, Paris, France, and Dr. Raymond Laurent, Tucamen, Argentina. It was hosted by Dr. Bendetto Lanza, at Museo Zoologica de "La Specola" in Florence. Drs. J. P. Bogart, Christina Richards, Margaret Stewart, and Mills Tandy attended from North America. ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

AMBYSTOMA TEXANUM (Smallmouth salamander). USA: TEXAS: Bell Co: small side canyon of Bear Creek, Fort Hood Military Reservation, 5.5 Km SW of Owl Creek community. 30 April 1978. R. W. Neck. Verified by R. W. Neck. Texas Memorial Museum (TNHC #48759). Found on protected (north exposure) slope of *Acer grandidentatum - Quercus muhlenbergia - Quercus texana* woodland. Small depression in bedrock (Cretaceous Edwards Limestome) available for oviposition micro-habitat. Medium-sized individual (s-v 39.0 mm, total 64.8 mm) found in deep soil/litter pocket upslope from boulder; microsite also supported relicit population of several terrestrial gastropods. Previous records from this area (Raun & Gehlbach, 1972, Amphibians and reptiles in Texas) were Lampasas Cut Plains crenophilic microhabitats now inundated by Belton Lake. This record documents survival of isolated populations above this reservoir in drainage basin of Leon River above Belton lake. Existence of *A. texanum* in this area is also of interest because habitat is more typical of *Plethodon glutinosus* which can be found in isolated mesic slopes and epigaeal microhabitats in Texas Hill Country northward to Bell County.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: NEW YORK: Jefferson Co: Township of Alexandria, beech-hemlock forest, ca. 60 m E of the intersection of N.Y. Route 12 and Cranberry Creek. 26 August 1976. P. J. Petokas. American Mus. Nat. Hist. (AMNH 104811). Verified by M. W. Klemens. This report provides more precise locality information than is presently available for range in the Thousand Islands region of New York. Bishop (1941, New York State Mus. Bull. 324:195) reported a Hobart College specimen marked "Thousand Islands, summer 1900," and Werner (1959, Copeia 1959(2):170-172) mentioned finding this species on the New York mainland, but did not give locality data. Neill (1963, Cat. Am. Amphib. Rept. 2:1-2) did not include this area in his description of the range of *Hemidactylium.*

Submitted by **PETER J. PETOKAS,** U.S. Fish and Wildlife Service, 100 Grange Place, Cortland, New York 13045 and **MAURICE M. ALEXANDER**, Department of Environmental and Forest Biology, SUNY College of Environmental Science and Forestry, Syracuse, New York 13210. ●

NECTURUS MACULOSUS (Mudpuppy). USA: MINNESOTA: Kanabec Co: (T 41N, R 23W, Sec. 33) in Snake River above Mora. 1976. J. I. Stewart. Preserved specimens housed at University of Minnesota Fisheries Department. About 100 individuals observed during spring, summer, and fall while electrofishing for smallmouth bass. Found under boulders near the margins of the river. Confirms presence in east central Minnesota (Breckenridge, 1944, *Reptiles and Amphibians of Minnesota*, University of Minnesota Press; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of East Central Minnesota - Region 3E).

Submitted by **JAMES I. STEWART** and **PHILIP A. COCHRAN**, Department of Entomology, Fisheries and Wildlife, University of Minnesota, St. Paul, Minnesota 55108. ●

ANURA

BUFO WOODHOUSEI WOODHOUSEI (Woodhouse's Toad). USA: TEXAS: Briscoe Co: Lake Theo. 13 June 1979. R. W. Neck. Verified by R. W. Neck. Texas Memorial Museum (TNHC 48760). Collected on shoreline of artificial impoundment immediately behind dam. Extends known range from adjacent Donley County.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: Briscoe Co: Dissected terrace top above Holmes Creek at upper end of Lake Theo. 4 October 1977. R. W. Neck. Verified by R. W. Neck. Texas Memorial Museum (TNHC 48761). Collected approximately 7 m above Lake Theo on overgrazed slope with scattered grass and scrub cover. Extends range approximately 100 km NW from Cottle County.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

HYLA GRATIOSA (Barking Treefrog). USA: TENNESSEE: Hardeman Co: 2.4 km NW Toone. 17 June 1969. Virginia M. Norton. Identified by William H. Redmond (University of Tennessee at Knoxville), verified by A. Floyd Scott (Austin Peay State University). Memphis State University Museum of Zoology, MSUMZ A2142. Incorrectly identified as *Hyla cinerea* initially (Norton, V.M. and M.J. Harvey. 1975. Herpetofauna of Hardeman County, Tennessee. J. Tennessee Acad. Sci. 50(4): 131-136.). First record for state west of Tennessee River, third known locality in Tennessee. Extends range ca. 130 km NW of nearest population (Alabama: Lauderdale County), ca. 220 km SW of nearest Tennessee population in Montgomery County, and ca. 320 km W of only other Tennessee population in White County (Scott, A.F. and D.F. Harker. 1968. First records of the barking treefrog, *Hyla gratiosa* Le Conte, from Tennessee.

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

PSEUDACRIS CLARKI (Spotted Chorus Frog). USA: TEXAS: Briscoe Co: North Prong of Little Red River, 7.3 km NW Lake Theo Dam. 3 October 1977. R. W. Neck. Verified by R. W. Neck. Texas Memorial Museum (TNHC 48763). Collected around plunge pool from stairstep breaks of Ogallala Formation. Extends known range from adjacent Armstrong County on north, but large gap still exists to southeast in drainage basins of Wichita and Pease Rivers.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). USA: KANSAS: Clark Co: 24 km N Ashland. 21 April 1979. R. Powell, H. Gregory, J. Parmerlee. Verified by J. T. Collins, University of Kansas Museum of Natural History. Bobby Witcher Memorial Collection, Avila College, BWMC 825, donated to University of Kansas Museum of Natural History (KU 183826). New county record extends range into the Red Hills (Collins, 1974. Amphibians and Reptiles in Kansas. UKMNH Publ. Ed. Ser. No. 1 pp. 61-63). Western chorus frogs were co-existing with spotted chorus frogs (*Pseudacris clarki*) in small pond (Smith, P.W. and D.M. Smith 1952. Amer. Midl. Nat., 48(1):165-180).

Submitted by **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Briscoe Co: Lake Theo. 5 October 1977. R. W. Neck. Verified by R. W. Neck. Upper reaches of Lake Theo support thriving population which is undoubtedly introduced as Lake Theo is artificial impoundment constructed in the early 1960's. This record is an extension of approximately 180 km up drainage basin of Red River to base of Eastern Caprock Escarpment.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

SCAPHIOPUS HOLBROOKI HURTERI (Hurter's Spadefoot). USA: ARKANSAS: Cleburne Co: 2.0 km NW of Greer's Ferry Lake on AR 16 at Edgemont, T11N, R11W, Sec. 7. 23 April 1966. Paul Elick. Verified by W.W. Byrd and V.R. McDaniel. Arkansas State Herpetol. Mus. (ASUHM 3816). First specimen known from central Arkansas and from the hiatus presently separating the ranges of *S. h. holbrooki* and *S. h. hurteri* (Dowling, H.G. 1957. Occ. Pap. U. Arkansas Mus. 3: 1-51; Conant, R. 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **CHRIS T. McALLISTER** and **V.R. McDANIEL**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467. ●

TESTUDINES

KINOSTERNON SUBRUBRUM HIPPOCREPIS (Mississippi Mud turtle). USA: Florida: Wakulla Co: St. Marks National Wildlife Refuge, 16.6 km E of Crawfordville. 6 May, 1979. R. Seigel, N. Seigel, and D. Niver. Verified by P. C. H. Pritchard. Univ. of Central Florida, uncatalogued. Extends range approximately 211 km E of previously recorded locality (Conant, 1975, a Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co; Boston). Adult male, carapace length 7.1 cm. P. C. H. Pritchard (pers. comm.) suggests some minor *K. s. subrubrum* influence is present in this specimen, indicating that the two subspecies intergrade over a wider area than previously believed. Additional collecting in the immediate area east of this locality would be useful in determining the extent of intergradation.

Submitted by **RICHARD A. SEIGEL**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, and **NADIA A. SEIGEL**, Department of Biological Sciences, University of Central Florida, Orlando, Florida 32816. ●

TERRAPENE O. ORNATA (Ornate Box Turtle). USA: TEXAS: Briscoe Co: Lake Theo. Prior to 17 May 1979. M. Robertson. Verified by R. W. Neck. Dead remains collected in association with Lake Theo. Subsequently on 15 June 1979, one DOR and one crossing road observed on FM 1065 within Quitaque city limits. Extends range from four or six contiguous counties.

Submitted by **RAYMOND W. NECK**, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744. ●

SAURIA

CNEMIDOPHORUS TESSELATUS (Colorado Checkered Whiptail). USA: TEXAS: Hutchinson Co: 1 km W of RR 1319 on County Road 3071 (35° 43' N 101° 35' W). 22 July 1979. Collected and identified by F.C. Killebrew. West Texas State University 4057. Extends range *ca.* 80.5 km north (Raun and Gehlbach, 1972. *Amphibians and Reptiles in Texas. A Taxonomic Synopsis, Bibliography, and County Distribution Maps*); new county record, and fills in distributional gap between previous localities in Potter County, Texas and Cimarron County, Oklahoma (Webb, 1970, *Reptiles of Oklahoma*. University of Oklahoma Press, Norman). Several other specimens were collected and released.

Submitted by **F. C. KILLEBREW**, Biology Department, West Texas State University, Canyon, Texas 79016. ●

COLEONYX VARIEGATUS BOGERTI (Tucson Banded Gecko). USA: NEW MEXICO: Hidalgo Co: Dump, 3 km W junction New Mexico Rts. 530 and 92, T19S, R21W, sec 14 or 15. 17 & 24 August 1977. Riley Springs, Riley Canyon, T18S, R20W, sec 20. 17 August 1977. D. G. Johnson. Verified by A. H. Price. New Mexico State University (NMSU 5216-5218). These localities are 20 km east of the nearest locality in Arizona and 75 km north of the northernmost previous locality in New Mexico (Axtell, 1974, Symposium on the Biological Resources of the Chihuahuan Desert Region, United States and Mexico, Proceedings and Transactions of the National Park Service, No. 3, p. 503) and extend the range of this species north of the Gila River in New Mexico (Dixon, 1970. *Coleonyx variegatus*. Cat. Amer. Amphib. Rept. 96.1-96.4).

Submitted by **ANDREW H. PRICE**, Department of Biology, Box 3AF, New Mexico State University, Las Cruces, New Mexico, 88003. ●

EUMECES ANTHRACINUS (Coal Skink). USA: TENNESSEE: Benton Co: 3.2 km S Eagle Creek. 13 April 1979. J. S. Sanders and J. S. Jacob. Verified by M. V. Plummer (Harding University). Memphis State University Museum of Zoology (MSUMZ R1578). First record from state west of Unaka Mountain Province in east Tennessee, represents third known locality and fourth specimen from state. Only known museum specimen of *E. anthracinus* from Tennessee. Extends range into west Tennessee ca. 100 km N of nearest population (in northeastern Mississippi), and ca. 360 km W of only other known localities in Monroe and Polk Counties in east Tennessee (Johnson, R. M. 1958. A Biogeographic Study of the Herpetofauna of Eastern Tennessee, Unpubl. Ph.D. Thesis, University of Florida; A. C. Echternacht and W. H. Redmond, pers. comm.). Specimen appears to be intergrade between *E. a. anthracinus* and *E. a. pluvialis*

(Mount, R. H. 1975. The Reptiles and Amphibians of Alabama, Auburn University). Collected under piece of roofing tin in hardwood riparian habitat. Herpetofaunal associates were *Scincella lateralis, Eumeces fasciatus,* and *Sceloporus undulatus.* The range of *E. anthracinus* has not been previously shown to extend into Tennessee (Conant, R. 1975. A Field Guide to the Amphibians and Reptiles of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **JAMES S. JACOB** and **J. STEPHEN SANDERS**, Ecological Research Center, Department of Biology, Memphis State University, Memphis, Tennessee 38152. ●

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: El Paso Co: El Paso. 3 September 1979. R. J. Long. Identified by A. H. Price. New Mexico State University (NMSU 5602). This specimen fills a hiatus between introduced populations 535 rd km to the west in Tucson, Arizona (Robinson and Romack, 1973, J. Herpetology 7(3): 311-312) and 697 rd km to the southeast in Del Rio, Texas (Davis, 1974, J. Herpetology 8(1): 77-80). It was collected on a residential building approximately 1.6 km from an oil refinery that was receiving shipments of pipe earlier in the summer from San Antonio, Texas, 948 rd km to the southeast, another location of a population of this species and a likely source for this introduction. Several other geckos were seen on the walls of the building by the residents in the weeks preceding the capture of this specimen, a hatchling. It is unknown whether or not they represent a viable population. It is to be expected that this species will eventually turn up in almost any town of sufficient size in the desert southwest.

Submitted by **ANDREW H. PRICE**, Department of Biology, Box 3AF, New Mexico State University, Las Cruces, New Mexico, 88003. ●

PHYLLODACTYLUS H. HOMOLEPIDURUS (Leaf-toed Gecko). MEXICO: SONORA: Punta Cirio (10 km SSE of Puerto Libertad). 21 March 1979. V. L. Tripi and J. E. Minnich. Identified by J. R. Dixon. Milwaukee Public Museum (MPM 18530). Northernmost record on the coast of Sonora. Previous closest record is "31 mi N Hermosillo" and previous northernmost record on Sonoran coast is "La Posa, San Carlos Bay" (Dixon, J. R., 1964. New Mexico State University Scientific Bulletin 64-1:1-139). Extends previous known range 160 km west-northwest and along the coast 260 km northwest. The juvenile female specimen (snout-vent length = 35 mm) was collected while inactive in the morning (9:00 A.M. MST) under granite boulder. Plant associates were *Idria columnaris* (boojum), *Pachycereus pringlei* (cardon), *Encelia farinosa* and numerous forbs (mainly *Lupinus*). Because of possible overlap with populations of *P. xanti* from islands in the Gulf of California (Dixon, J. R., 1964, *op. cit.,* and 1969, Catalogue of American Amphibians and Reptiles 79:1-2), the following diagnosis by J. R. Dixon is presented: postmentals 2, followed by 6 granules, contacting 2 anterior labials on each side; orbital scales across center of eyes 18-19 (palpebrals not included); third labial snout scales 20; longitudinal venter scales 32; transverse venter scales 58; tail with 2/0 reduction on anterior fourth; basal tail tubercles in 4 rows; dorsal tubercle rows 12 (14 past mid-body); tubercles from rear of head to base of tail 33, from axilla to groin 21; scales from eye to nostril 11; internasal border scales 7; fourth toe lamellae 14.

Submitted by **JOHN E. MINNICH**, Zoology Department, University of Wisconsin—Milwaukee, P. O. Box 413, Milwaukee, Wisconsin 53201. ●

SERPENTES

ARIZONA ELEGANS OCCIDENTALIS (California Glossy Snake). MEXICO: BAJA CALIFORNIA DEL NORTE: 20.9 km N jct Mex. Rt. 1 and Mex. Rt. 1 (to Bahia de los Angeles). 1 July 1978. W. Seifert. Dallas Museum of Natural History (DMNH 4763). 8 km N jct Mex. Rt. 1 and Mex. Rt. 1 (to Bahia de los Angeles). 1 July 1978. W. Seifert. (DMNH 4765). Previously only recorded along the west coast of Baja California as far south as El Rosario (Dixon and Fleet, *Arizona elegans* SSAR Cat. Amer. Amph. Rept. 179.1-179.4). These specimens offer a link with *A. e. pacata* which occurs only a few kilometers south and west of this reported locality. However, their dorsal body blotch count yields no evidence of intergradation with that race.

Submitted by **WAYNE SEIFERT**, Division of Lower Vertebrates, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226. ●

REGINA GRAHAMI (Graham's Crayfish Snake). USA: TEXAS: Hemphill Co: 1 km S of Canadian River on U.S. 83. 12 June 1978. G. Rhea. Verified by F. C. Killebrew. West Texas State University Natural History Collection 4056. Extends range *ca.* 130 km northwest (Webb, 1970. *Reptiles of Oklahoma,* University of Oklahoma Press, Norman).

Submitted by **F. C. KILLEBREW** and **MILES RHEA**, Biology Department, West Texas State University, Canyon, Texas 79016. ●

STORERIA DEKAYI TEXANA (Texas Brown Snake). USA: TEXAS: Navarro Co: farm of C. J. Green off of Business Hwy 75, Corsicana. 26 October 1979 by Macon Edwards, Navarro College. Verified by Thomas Vance, Navarro College, Corsicana (NC 1979.10.26.1S). First record for Navarro County which partly fills the area between most of the surrounding counties (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist. Bull. 2:1-61). Specimen dehydrated but identifiable.

Submitted by **THOMAS VANCE** and **MACON EDWARDS**, Biology Department, Navarro College, Corsicana, Texas 75110. ●

THAMNOPHIS EQUES MEGALOPS (Mexican Garter Snake). USA: NEW MEXICO: Hidalgo Co: 8.3 km E of Virden in Gila River. July 1973. Kim Mello. Identified by A. H. Price. New Mexico State University (NMSU 5377). This specimen apparently is the second from the state and the first in this century (Conant, 1974, Symposium on the Biological Resources of the Chihuahuan Desert Region, United States and Mexico, Proceedings and Transactions of the National Park Service, No. 3, pp. 464 & 471). This species probably occurs throughout the Gila River and its tributaries in New Mexico wherever permanent water remains.

Submitted by **ANDREW H. PRICE**, Department of Biology, Box 3AF, New Mexico State University, Las Cruces, New Mexico 88003. ●

GEOGRAPHIC DISTRIBUTION OF TWO COLOR MUTANTS OF THE CORN SNAKE, *ELAPHE GUTTATA GUTTATA*

Elaphe guttata guttata ranges from southern New Jersey southward along the Coastal Plains through the Florida Keys, and westward to southern Louisiana. The range also includes the southern and eastern parts of Tennessee and disjunct populations in Kentucky (Conant, 1958).

Two color mutations have been reported in wild populations. Hensley (1959) described the first as complete albinism, referring to animals with red or pink eyes and without apparent melanin in body patterns. He also notes the melanin concentration varies, so definition of albinism has been left to individual interpretation. Since other pigments are present and a second color mutation has been identified, the snakes lacking melanin are more properly named amelanistic partial albino or amelanistic. The second color mutation involves the failure to produce the red and much of the yellow pigments, and should be referred to as an anerythristic partial albino or anerythristic. Both mutations, amelanistic partial albino (Bechtel and Bechtel, 1962) and anerythristic partial albino (Slemmer, 1973), have been bred in captivity and are inherited as autosomal recessives.

Elaphe g. guttata is a popular captive animal due to its docile disposition and its ability to thrive when given proper care. Since many herpetologists are breeding snakes to produce recessive color characteristics, there is always the chance that captive bred color mutants or carriers may enter the gene pool, thus altering their naturally occurring frequency. Therefore, a survey of mutant locations in the wild is significant. Furthermore, when this study was begun, all known anerythristic specimens were from one general area in Florida. One purpose of this survey was to find out if this was their sole locality.

Hensley (1959) assembled all known records of albinism reported in the literature and

Fig. 1. Known collecting sites for amelanistic partial albinos, *Elaphe g. guttata*.

Fig. 2. Known collecting sites for anerythristic partial albinos, *Elaphe g. guttata*.

those unpublished records up to that time. He listed four albino *Elaphe guttata* in his publication.

Mutant specimens were located by surveys of published material and collections as well as contacting individuals known to have collected them or who were aware of mutants in the field.

The collections surveyed were either located within the range of *Elaphe g. guttata* or were considered to be large and well-known enough to merit inclusion in this report. Thirty-one letters were sent to museums, universities, and colleges. Ninety per cent responded. To avoid false positive identifications of the anerythristic corn snake, a colored photograph of a live specimen was enclosed with the letter of inquiry. The following collections were inspected: Florida State Museum at Gainesville, Florida; Savannah Science Museum located in Savannah, Georgia; and Tall Timbers Research Station near Tallahassee, Florida. Also, Means (1978 personal communication) at Tall Timbers verified that no mutants were present in the Florida State University collection.

The geographic distribution of amelanistic mutants is shown in Fig. 1. The total number reported is ten; six from Florida, three from Tennessee, and one from North Carolina. Fig. 2 locates the anerythristic mutants. The total number reported is sixteen plus an unknown number of young. Two of these specimens are from Georgia and all others have been located in five contiguous counties in the southern tip of Florida.

The following represents data for the color mutant *Elaphe g. guttata* reported here.

Amelanistic partial albinos.

FLORIDA - Dade County, Hialeah. Gravid female caught in 1962 and two hatchlings had no melanin present. Specimen collected by Louis Porras, The Shed, 6932 N.W. 46th Street, Miami, Florida.

Franklin County, near Lanark. Specimen collected after being hit on highway U.S. Rt. 98 on 6 May 1972. Reported by D. Bruce Means, Tall Timbers Research Station, Tallahassee, Florida.

Marion County, Silver Springs. Reported by Hensley (1959).

Monroe County, Key West. Specimen brought to Miami Serpentarium. Reported by Louis Porras.

Sarasota County, outskirts of Myakka State Park. Collected July 1973 by Richard Bartlett, 146 North Brook Road, Springfield, Massachusetts.

NORTH CAROLINA - Stanly County, near Albemarle. Reported by Hensley (1959).

TENNESSEE - Obion County, Reelfoot Lake. Two juvenile specimens reported by Hensley (1959).

Shelby County, outside Memphis. Specimen collected in 1973 and reported by Louis Porras.

Anerythristic partial albinos.

FLORIDA - Collier County, south of Immokalee. Specimen collected on Rt. 858 on 6 January 1973 by Bob Wallen, 11324 Snowfall court, Tampa, Florida.

Dade County, west of Homestead. Collected about 1958. Reported by Louis Porras.

Dade County, 35 miles west of Miami. Collected in summer of 1968. Reported by Louis Porras.

Dade County, Homestead. Collected in 1973. Reported by Louis Porras.

Dade County, 15 miles northwest of Homestead. Collected in summer of 1977. Reported by Louis Porras.

Dade County, Rt. 27 at entrance to Everglades National Park. Collected by Joe Granado, 5509 SW Second Street, Miami, Florida.

Hendry County. Collected in fall of 1976 by John Rindfleish, Box 172, Palm Beach, Florida.

Hendry County. Specimen collected 10 January 1978 by Dick Flood, Okefenokee National Wildlife Refuge, Waycross, Georgia.

Hendry County, south to southwest of Clewiston. Three specimens purchased from Thompson Zoo in Clewiston by Louis Porras.

Hendry County, near Devil's Garden. Gravid female had unknown number of young without red pigment. Collected by Louis Porras.

Lee County, Tice. Specimen collected 2 June 1969, (Florida State Museum, 29082). Collected by John Martins.

Palm Beach County. Two specimens collected in 1977 by Louis Porras.

GEORGIA - Chatham County. Adult male collected July 1978. Reported by Bobby Mullis, Savannah Science Museum, Savannah, Georgia. Collected by Tom Roe.

Effingham County, Meldrim Road 0.2 miles north of Chatham County line. Collected by Charles S. Willis, 13 March 1977. Adult male, DOR (Savannah Science Museum, 77.5482).

One can only speculate why more aberrant *Elaphe g. guttata* have been reported from Florida. It may be due to more intense collecting, a year-round collecting period, available resources for identification, a higher incidence within the gene pool, or a combination of some of these. The scarcity of anerythristic specimens reported outside of Florida may be due to misidentification of this abnormality. Immature *Elaphe obsoleta* occurring throughout most of the range may be confused with this mutant.

Sincere thanks are expressed to H. Bernard Bechtel for his support, advice, and helpful criticism; J. Jay Whitesell for reading the paper and offering suggestions; and the respondents for their cooperation.

TO ORDER:

To SSAR members, *if ordered before 1 August 1980* . . . . . ☐ $10 paperbound* ☐ $14 clothbound

To non-members; Institutions; all orders after 1 August . ☐ $20 paperbound* ☐ $24 clothbound

**Persons wishing to change orders to clothbound copies can remit an additional payment of $4.*

Prices include packing and shipping world-wide. Address orders to Dr. Henri C. Seibert, Department of Zoology, Ohio University, Athens, Ohio 45701, U.S.A. Receipt sent on request only. Mark here ☐ if you wish to have a complete pricelist of SSAR publications including the *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles,* and the publications of The Ohio Herpetological Society.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

LOCALITY RECORDS OF *RHINOCHEILUS LECONTEI* IN THE UNITED STATES AND MEXICO

The locality records reported below include all records available at the time of publication of the species account for *Rhinocheilus lecontei* (Medica, 1975). Additional records include fossil localities in Texas (Rogers, 1976); New Mexico (Van Devender and Worthington, 1978); Arizona (Van Devender et al., 1977); Arizona and California (Van Devender and Mead, 1978); and Nevada (Van Devender, pers. comm.). Additional published county and state records include: Kansas (Collins and Caldwell, 1976); Texas (Hambrick, 1975; Karges, 1978; Mather and Dixon, 1976); Oklahoma (Mather, 1978); and Zacatecas, Mexico (Frost, 1978). All the above recent records are included in the list below in addition to numerous unpublished county records for which specimens are presently in collections whose records were made available to me.

Rhinocheilus lecontei has been recorded in the following states and counties in the United States and Mexico: *ARIZONA*: Cochise, Gila, Graham, Maricopa, Mohave, Pima, Pinal, Santa Cruz, Yavapai, Yuma; *CALIFORNIA*: Alameda, Fresno, Imperial, Inyo, Kern, Kings, Lassen, Los Angeles, Madera, Orange, Riverside, San Benito, San Bernardino, San Diego, San Joaquin, San Luis Obispo, San Mateo, Santa Barbara, Stanislaus, Sutter, Tulare; *COLORADO:* Baca, Powers; *IDAHO*: Elmore; *KANSAS*: Barber, Clark, Comanche, Ford, Hamilton, Harper, Meade, Morton, Seward, Stanton; *NEW MEXICO*: Bernalillo, Chaves, De Baca, Dona Ana, Eddy, Grant, Guadalupe, Harding, Hidalgo, Lea, Lincoln, Luna, Otero, Quay, Roosevelt, Sandoval, San Miguel, Sierra, Socorro, Valencia; *NEVADA*: Churchill, Clark, Elko, Esmeralda, Lincoln, Mineral, Nye, Washoe; *OKLAHOMA:* Alfalfa, Beaver, Blaine, Comanche, Custer, Dewey, Grandy, Greer, Harmon, Harper, Jackson, Love, Woods, Woodward; *TEXAS:* Andrews, Archer, Armstrong, Atascosa, Baylor, Bee, Bell, Bexar, Borden, Bosque, Brewster, Briscoa, Brooks, Brown, Burnet, Callahan, Cameron, Childress, Clay, Cochran, Coke, Colesman, Collingsworth, Comal, Comanche, Concho, Coryell, Cottle, Crane, Crockett, Crosby, Culberson, De Witt, Dickens, Dimmit, Duval, Eastland, Ector, Edwards, El Paso, Erath, Foard, Gaines, Garza, Gillespie, Gonzales, Hamilton, Hardeman, Hartley, Haskell, Hays, Hemphill Hidalgo, Hood, Howard, Hudspeth, Hutchinson, Irion, Jack, Jeff Davis, Jim Wells, Jones, Karnes, Kent, Kimble, King, Kleberg, Knox, Lampasas, La Salle, Live Oak, Llano, Lubbock, Lynn, Martin, Mason, Maverick, McCulloch, McLennan, McMullen, Medina, Menard, Midland, Mills, Mitchell, Montague, Motley, Nueces, Ochiltree, Palo Pinto, Parker, Pecos, Presidio, Randall, Reeves, Runnels, San Patricio, San Saba, Scurry, Shackelford, Starr, Stephens, Stonewall, Sutton, Tarrant, Taylor, Terrell, Throckmorton, Tom Green, Travis, Uvalde, Val Verde, Ward, Webb, Wheeler, Wichita, Wilbarger, Williamson, Wilson, Winkler, Wise, Young, Zavala; *UTAH*: Beaver, Carbon, Juab, Kane, Millard, Tooele, Washington; *MEXICO*: Baja California Norte; Baja California Sur (Cerralvo Island); Chihauhua; Coahuila; Durango; Jalisco (exact locality unknown); Nayarit; Nuevo Leon; San Luis Potosi; Sinaloa; Sonora; Tamaulipas; Zacatecas.

ACKNOWLEDGEMENTS

ENYALIOSAURUS QUINQUECARINATUS (GRAY) AND *LEPTODEIRA NIGROFASCIATA* GÜNTHER IN EL SALVADOR

Recent herpetological work in El Salvador, in connection with the preparation of treatments of the lizards and snakes of the country, has demonstrated the presence of two species new to the herpetofauna of El Salvador. These additions are discussed below.

ENYALIOSAURUS QUINQUECARINATUS (GRAY)

The distribution of *Enyaliosaurus quinquecarinatus* is disjunct, with isolated populations having been recorded from the Isthmus of Tehuantepec, Oaxaca, Mexico (Bailey

1928), Honduras (Günther, 1885; Meyer and Wilson, 1973) and Nicaragua (Villa and Scott, 1967).

Several specimens are now available from El Salvador. The localities from which this lizard has been collected are: No specific locality (DBUES 64); Loma El Salamar, Cantón Calavera, Cacaopera, 6 Km SE Corinto, Depto. Morazán (MHNES 361); Cantón La Joya, 3 ½ Km W Tejutepeque, Depto. Cabañas (NH 235, 244-248). These localities are below 800 m in the Subtropical Dry Forest formations of Holdridge (1975). The vegetation at these localities consists primarily of *Curatella americana* and *Karwinskia calderoni*. The soil abounds with stones.

The Salvadorean specimens agree well with Gray's (1842) original description of *E. quinquecarinatus* and also with that given by Bailey (1928). The specimens lack a dewlap and have a strong transverse gular fold. Supralabials vary from 7 to 10; infralabials, from 6 to 10. The suprabrachials scales are smooth and the central row of caudal spines is equal in size to the lateral series, usually 9 enlarged dorsal scales on the 4th caudal whorl. The middorsal crest is low, extending to or near to the sacrum. Number of dorsal scales in midline 40 to 84 (average 65). Femoral pores vary from 6-5 to 9-8.

Males range from 126 to 169 mm (152 mm) in snout-vent length and from 318 to 385 mm (350 mm) in total length; females, from 83 to 112 mm (100 mm) in snout-vent length and from 195 to 250 mm (226 mm) in total length. The smallest juvenile, a female, has a snout-vent length of 83 mm and a total length of 195 mm.

The color of the adults in life was as follows: ground color gray; dorsum of head olive gray; usually with whitish-gray, black or orange dots; body with brown or black crossbands, narrowing laterally, and extending onto venter, where they almost meet midventrally (in some specimens these bands may be more or less fused dorsolaterally, but usually remain distinct middorsally and laterally); interspaces between crossbands olive yellow to olive green dorsally; body flecked with whitish-gray between the crossbands laterally; dorsum of tail with olive yellow to olive gray crossbands alternating with dark brown ones; limbs with irregular transverse dark brown to black bands, flecked with olive green to whitish-gray dorsally (in some specimens the upper surfaces of the limbs are completely black with whitish gray flecks); chin and throat with dark brown to black spots or blotches; gular region and chest olive green to yellow green (in some individuals the gular region is spotted or black); venter gray; undersides of limbs with dark brown to black flecks.

The color of the juveniles in life was as follows: ground color olive gray; dorsum of head olive green, faintly spotted with dark brown; body with conspicuous narrow, dark brown crossbands, sometimes discontinuous laterally but extending onto venter as a row of spots; olive green middorsally between the bands; upper surfaces of limbs with dark brown to black blotches or with conspicuous transverse black bands; chin, throat, and gular region olive gray to whitish-gray, with longitudinal blackish streaks; underside of limbs with black spots.

Villa and Scott (1967) indicated that these lizards have arboreal habits. However, in El Salvador they seem to be primarily terrestrial, climbing in trees occasionally to forage for food. I have found both juveniles and adults under small, flat rocks, slabs of limestone and in loose rock fences.

The juvenile of *E. quinquecarinatus* from Nicaragua discussed by Villa and Scott (1967) had a bright green dorsal ground color, which becomes duller later in life. The color thus differs from that of juveniles from El Salvador. Perhaps the duller color of the Salvadorean juveniles adapts them better to the rocky environments they inhabit in El Salvador.

LEPTODEIRA NIGROFASCIATA GÜNTHER

Duellman (1958) recorded the range of *Leptodeira nigrofasciata* as comprising the Pacific lowlands from Guerrero, Mexico south through Guatemala, Hounduras, and Nicaragua to Costa Rica. A single specimen is now available from El Salvador. The locality is km 56 on the road to La Libertad, between Mizata and Bocana La Perla, 10 m, Depto. La Libertad. The specimen came from an area that was originally in the Subtropical Moist Forest formation of Holdridge (1975); presently there are only relicts remaining of this forest.

The Salvadorean specimen (MHNES 488) is a male with the following characteristics: ventrals, 175; anal plate divided; subcaudals, 75; dorsal scales smooth; dorsal scale reduction formula

$$19\ \frac{8+9(125)}{8+9(127)}$$

17 (175); supralabials 8-8, with 4th and 5th entering orbit; infralabials 10-10; loreal single; preoculars 2-2; postoculars 1-1; temporals 1+2+3; total length, 517 mm; tail length 130 mm.

The color in life was as follows: dorsal ground color cream, with 17 dark brown blotches, extending laterally onto the tips of the ventrals; interspaces greenish cream, varying from one to four scales in length; first interspace creamy white, straight-edged, extending three scales behind parietals; no intercalary spots; tail with 10 transverse dark brown bands; venter cream; dorsum and sides of head dark brown; chin and throat grayish brown; chin shields spotted with dark brown medially.

The above description agrees well with that given by Duellman (1958), except that he gave the range in total length in males as from 202-486 mm; the specimen herein reported exceeds the upper end of this range by 87 mm.

ACKNOWLEDGEMENTS

The authorities at the following institutions allowed me to examine material in their collections: Museo de Historia Natural de El Salvador (MHNES), and the Departamento de Biologia, Universidad de El Salvador (DBUES); Dr. Larry D. Wilson provided bibliographic assistance and suggested improvements to the manuscript; Sres. Roberto Hidalgo, Ernesto Hidalgo, Gonzalo Hidalgo and Pedro Galicia helped me in the field; Maria I. Hidalgo typed several drafts of the manuscript. To all go my sincere thanks.

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted.

ACKNOWLEDGEMENTS: I would like to express my thanks to the following individuals who have generously given their time to scan journals or submit titles to sections of Current Literature published in HR 10(1) to date. They are as follows:
K. Adler, J. Applegarth, G. H. Balazs, L. E. Bayless, A. Bea, J. F. Berry, R. Bezy, R. M. Blaney, R. C. Boycott, D. G. Broadley, E. E. Brown, U. Caramaschi, G. Casas-Andreu, J. M. Cei, J. E. HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

"SIOP"—A NEW NON-VENOMOUS POISON SNAKE

"Over 700,000 children swallow poisonous substances each year. Most children who swallow poisons are under 5 years of age"—thus reads some of the poison facts by HAPPY, an organization from Normal, Illinois, which is attempting to eliminate accidental poisoning in children. Working with over 15 poison control centers in the midwest and south, HAPPY is marketing products which are designed to educate adults and children about the dangers of poisonous substances such as medicines, plants, insect spray poisons, household cleaning agents, gasoline and petroleum products, paint and polishes, cosmetics, and strong chemicals. Most Americans would generously accolade any organization designed to reduce or eliminate accidental poisonings, so why should herpetologists be expressly interested in the workings of this organization?

Herpetologists, as well as other conservationists, should be aware that a new and psychologically tested motif which symbolizes danger and poison is a caricature of a snake. The snake, named "Siop," is the trademark of the HAPPY poison prevention campaign. No—Siop means "poison" spelled backwards. The snake is definitely not a friendly-looking creature. The snake is coiled twice and has an upraised and disproportionally large head with large ominous eyes and round pupils. The face has a frowning mouth with two exposed, long, closely adjacent fangs. An additional design which resembles the pointed ends of two men's neckties placed side by side, appears on the snake's forehead and accentuates the downward pointing and fierceness of the fangs. Siop is colored green and appears in the center of an orange circle surrounded by a black ring. Emergency phone numbers and the name of the sponsoring poison control center appear within the black ring. The sclera of the eyes and the fangs are white. Interestingly, except for the fangs, the characteristics that most herpetologists might recognize to be indicative of a potential poisonous snake are not presented. For example, the tip of the tail is exposed but bears no rattle, the pupils are round and not elliptical, facial pits are not present, the head is not triangular, and color patterns (red, yellow, black rings) are not present.

Siop thus apparently is not a venomous North American snake. Why then was he chosen for this despicable position? The answer is not obvious. First of all, Siop was not designed to warn the individuals about the danger of venomous snakes. Rather Siop was designed to be used as a "symbol" to indicate a potentially dangerous substance. Thousands and thousands of Siop the "symbol" stick-on labels have been distributed to hospitals, schools, nursing homes, and community organizations. His presence on medicine bottles, rat poison, lye soaps, and other household items is preventing poisoning in both children and adults. Secondly, the Siop symbol and colors were chosen by psychological testing in competition with old and new symbols. For example, Siop was more effective in creating an adverse reaction in children than the old skull and crossbones symbol. Commercialism has made the familiar skull and crossbones just that—too familiar, and it now signals "pirates and fun" to many youngsters. The symbols used by other poison control centers have also recently suffered from commercialism. For instance, Mr. Yuk is the poison symbol created by the Children's Hospital of Pittsburgh and used by its network of poison control centers. Mr. Yuk is a round green circle which represents a face. The face has frowning closed eyes and a frowning mouth with a protruding tongue extending downwards. His expression descriptively fits the slang work "Yuk!" Unfortunately, the overuse of similar designs exhibiting a smiling face with captions reading "have a happy day" or a frowning face reading "hope you feel better soon" are probably having a negative impact upon the effectiveness of Mr. Yuk. Third, Siop also is less expensive to use. Strong copyright and other technical contracts which are designed to reduce the unauthorized use of such poison logos often add considerable expense to most poison control programs. In summary, Siop was chosen because it is a psychologically ominous symbol which is easy to recognize, less expensive, and less familiar commercially.

Most ophiologists, on the other hand, become quite ired at the use of a snake, symbol or not, which is designed to create an adverse and negative reaction about snakes. The reinforcement of negative thoughts and false conceptualizations about snakes, we fear, might create animosity towards an already overhated creature. We argue that Siop might establish a new generation of hardened snake-phobes in the future and likewise stir the "dragons of Eden" (Carl Sagan,

Ballantine Books) within adults today. Most of us would like for the American public to think of the snake as the two entwined serpents on the staff of the caduceus—the symbol of healing and the physician, instead of Siop the poison bearer. Can we afford to overlook another onslaught (however subtle) against the snake, even though Siop was never intended to be a snake? Conversely, Siop is very effective in his role and many parents are grateful. Can we afford not to have a Siop?

MORRIS K. JACKSON
Department of Anatomy
Louisiana State University
Medical Center
Box 33932
Shreveport, Louisiana 71130

Dear Dr. Pisani:

Dr. Jackson has presented a knowledgeable argument on use of an alternate symbol to suggest danger, and the advantages when the figure is manually applied to a poisonous substance. I would like to comment further on the development of the SIOP Program and present the findings of a study we conducted to test childhood attitudes toward snakes as related to the Program.

As Dr. Jackson pointed out, SIOP is not a real snake, but rather a characterized snake-like drawing designed and tested by Masters degree candidates in Design and Psychology at Illinois State University, Normal, Illinois.[1,2] The snake was chosen among many animals due to its world-wide distribution, making it easily recognizable by even the youngest children in most countries. The SIOP figure is a construction of shapes chosen as most basic through perception studies in children.[3,4] Green was chosen because it has been shown to be the color most repulsive to our target age group (I-5 year olds).[5,6,7] The color orange focuses the child's eyes on the symbol, thus competing successfully with the graphics on the poison label.

During the educational portion of the program, the children are taught to selectively identify and avoid the character SIOP when it is attached to a product. The same selective approach is used when teaching children or adults to avoid other dangerous animals, plants, etc. By identifying unique characteristics, an individual is taught to avoid certain species of an animal or plant without condemning the entire order.

The SIOP symbol is meant to be used only in conjunction with the other materials of the poison prevention program. Parents must actively teach their children to avoid poisonous containers to which SIOP has been applied. Parents must also learn and practice our other safety rules (i.e., use only childproof caps) to avoid the senseless tragedy associated with childhood poisoning.

Recently, in Springfield, Illinois, an attitudinal study was conducted to test whether the SIOP Program negatively influenced childhood conception of snakes. The sample for this study was made up of 90 three and four year old children from four different nursery school classrooms. Two of the classrooms were used as an experimental group and two as the control, with 45 children in each group.

The pretest and posttest consisted of a 16 item questionnaire (Figure I). The first two questions helped establish rapport between the child and the experimenter and also helped to introduce the subject matter to the child. An explanation for question two enabled the experimenter to determine an encounter with a live or fictional snake. Questions three through nine related to the child's attitudes toward snakes and were noted with yes or no answers. Questions 10, 11 and 12 pertained particularly to the Siop Program. Questions 12 through 16 involved showing the child black and white drawings of snakes: (12) Siop, (13) crawling coral snake, (14) "fanged" rattle snake, (15) coiled western racer, and (16) coiled, fanged rattle snake.

The educational program involved a three day presentation, involving 15 to 30 minutes of instruction and activities per day. Materials used during the first day included two puppets (Happy and Siop), five household products (3 poisonous and 2 nonpoisonous), and a bulletin board illustrating numerous household products. The second day's lesson included an activity book for each child and five flash cards of three poisonous and two nonpoisonous products. The third day's lesson was supplemented with an antidote chart, a guide to poisonous plants, home safety check list, Siop warning labels, and a parent-teacher guide for each child to take home.

Procedures for the study were as follows:

1. **Pretest.** Each child was taken individually into a room away from the other children. The experimenter asked the child's name and age, and then gave the following explanation: "I'm going to ask you some questions I'd like you to answer for me." The experimenter then proceeded to ask the questions, noting responses. After question 11, the experimenter stated, "Now we are going to look at some pictures." The experimenter then showed the child the pictures, one at a time. After showing each picture, the experimenter asked, "Do you think this is a picture of a snake?" If the child's response was "yes" the experimenter asked, "Is this a good snake or a bad snake? Why?" If the child's response was "no" the experimenter then asked, "What do you think this is?" and noted the response in the space provided on the questionnaire.
2. **Educational Program.** The educational program was administered in two of the four classrooms three to five days after the pretest.
3. **Posttest.** The posttest was administered exactly as the pretest three weeks after the pretest in both the experimental and the control groups.
4. **Scoring.** One point was given for the following: A "no" answer for questions 3, 6, 7, and 9. A "yes" answer for questions 4, 5, and 8. "Good" as an answer for questions 13, 14, 15, and 16. The pretest scores were subtracted from the posttest scores and the resulting difference scores were used in the data analysis.

The study was set up in a simple randomized design. A t ratio was computed on the pretest - posttest difference score. Significance was set at the .01 level.

The results from the analysis of data suggest that there was no significant difference between the groups tested. The mean difference score for the experimental group was .40 and for the control was .47. No significant difference between the two group means was established ($t = .0256$).

The data collected in the study indicated that the SIOP Program has no significant effect on a child's attitudes toward snakes. Neither does the program have a significant effect on their conception of good and bad snakes.

As discussed, the SIOP Poison Prevention Research and Education Program is based on thorough research and creates no negative childhood attitudes toward snakes. The pro-

gram has been proven effective due to the dramatic reduction of accidental poisonings in those communities where the program has been implemented.

To the Poison Control Center Staff at Brokaw, the answer to Dr. Jackson's final questions is readily evident. Where the health and welfare of our children is involved, we can ill afford not to have a SIOP.

A SHELLED EGG IN THE CLOACAL BURSA OF A TURTLE *KACHUGA TECTUM TECTUM*

Presence of shelled eggs in the body cavity of turtles has been occasionally reported (Cagle, 1944, *Copeia*. p. 60; Cagle and Tihen, 1948, *Copeia*. p. 61; Duda and Gupta, 1978, *Herpetol. Rev.* 9(2):46; Risley, 1933, *Papers. Mich. Acad. Sci.*, Arts & Letters *17*:685-711) but their occurrence at other abnormal sites within the body of a turtle has been reported only once before (Dobie, 1968, *Herpetologica, 24*(4):328-330).

On 22 April 1977, a fresh water turtle, *Kachuga tectum tectum* was dissected for routine gonadal studies. Upon opening the turtle, a shelled egg was found lying inside its highly distended right cloacal bursa (Fig. 1). The ovaries looked spent and showed the presence of 11 ruptured follicles (7 right: 4 left) all of which were at nearly the same stage of differentiation into corpora lutea. The oviducts were fully developed but did not contain any eggs. The turtle had been captured four days earlier from a slow running stream 18 KM southwest of Jammu City (J. K. State, India). In its weight and measurements (weight 603 gm; carapace 182 x 170 mm; plastron 157 x 137 mm) and external and internal features, the turtle seemed a healthy and normal female.

Figure 1.

In view of the number of ruptured follicles in the two ovaries, the turtle had obviously ovulated 11 eggs but laid only 10, the 11th being apparently the one that had pushed its way into the cloacal bursa. The ill-fated egg was 38 mm in its longest axis and 21 mm in its maximum girth, in which dimensions it compared favourably with normal eggs (size range 23-45 x 15-30 mm) of the species. Additionally, a lot of fecal matter was seen to have nearly completely filled the urinary bladder and partially filled the cloacal bursa containing the egg. The left side cloacal bursa was in a collapsed state and was empty.

Dobie (*op. cit.*) attributed the abnormal placement of eggs in the urinary bladder to some carapaceal deformity and consequent crowding of reproductive structures in *Macroclemys temnicki*. In our specimen of *Kachuga t. tectum*, on the contrary, the carapace and arrangement of internal viscera were normal and hence could not have contributed to the abnormal movement of the egg into the cloacal bursa. Moreover, Dobie's speculation that "simultaneous movement of two eggs from opposite oviducts into the cloaca could have forced one egg . . . into the urinary bladder," and the presumption that "the unusual events . . . occurred twice, probably in similar fashion" to explain the occurrence of two shelled eggs in the urinary bladder in his turtle seem highly improbable.

Thus in view of what has been said above, the presence of shelled eggs in such unorthodox situations as reported appears to be purely accidental unless there is some morphological evidence to support an alternative. Presence of fecal matter in the urinary bladder and the cloacal bursa could be an outcome of a likely blockade in the cloacal passage created by the awkward position of the egg inside the distended bursa.

The specimen used in this study is in the collection of the Museum of the Department of Bio-Sciences, University of Jammu under catalogue No. JUBR-49.

FIELD METHODS FOR SAMPLING THE DIETARY COMPONENTS OF GREEN TURTLES *CHELONIA MYDAS*

The dietary components of *Chelonia* and other genera of sea turtles have not been adequately defined for most populations. While green turtles are known to be predominantly herbivorous, only limited information exists on the types of marine flora seasonally utilized by different age-groups at the geographically separated feeding pastures. Hirth (1971) summarized the published knowledge of the food of green turtles. Except for first-hand observations of turtles actively feeding, these determinations are based exclusively on analyses of stomach contents obtained from dead specimens that were either taken directly by fishermen and researchers, or salvaged after mortality resulting from other causes. The endangered status of most sea turtle populations presently imposes constraints on the direct and permanent collection of individuals for food determinations, unless such research is carried out incidental to existing turtle fisheries. Even then, an inherent limitation of this method is that it only allows for the sampling of an individual once. Stomach contents removed from stranded or other turtles found under aberrant circumstances have the additional disadvantage of possibly not being representative of the food sources normally utilized. When turtles are observed directly from shore, it is usually difficult to actually view what transpires beneath the surface where feeding takes place. The use of scuba for underwater observations has also been generally unsatisfactory due to the disturbance caused to natural behavior. Problems associated with the unobscured viewing of turtles feeding in the wild may, however, eventually be overcome through the use of closed-circuit underwater TV cameras positioned at strategic sites.

The need for further investigations of the food of all sea turtles in their respective regions has recently been emphasized by Schulz (1975). In the Hawaiian Islands (18°55'N, 154°49'W to 28°15'N, 178°20'W), life history research of the *Chelonia* has focused on aggregations of turtles in inshore feeding pastures throughout the 2,600 kilometer Archipelago, and non-injurious methods have been developed for field sampling of dietary components. The objective of this paper is to describe these techniques so that they may be used on *Chelonia* in other areas, and tested for effectiveness on the other genera of sea turtles. Although the methods employed are relatively simple, they have not been previously described for use on sea turtles.

Sampling Methods

Samplings of dietary components are carried out on green turtles that have been captured alive by one of the following techniques: 1) grasping the animals underwater by hand with the aid of scuba; 2) restraining the animals with long-handled scoop nets used from shore or from a small boat; 3) entangling the animals in large mesh nets set at regularly frequented sites. In each case, precautions are taken to prevent injury or undue stress.

After capture, a turtle is placed on its back with the mouth maintained in an open position by inserting a semirigid object between the upper and lower jaws on one side. A flexible plastic measuring tape folded to the appropriate dimension has been found suitable for such purposes. The mouth is then inspected visually for the presence of food material. If the turtle has been feeding immediately prior to capture and removal from the water, such material will frequently be present in relatively large quantities and can be easily removed. This retention of food in the mouth appears to be due to the inability of green turtles to swallow while out of water. Even when feeding has not been taking place, small particles of identifiable food may still be found adhering to the horny palate.

Following an inspection of the mouth, the stomach contents are sampled by inserting a flexible plastic tube through the esophagus into the stomach with subsequent moderate aspiration, either orally or with a syringe. For turtles 35 to 55 cm in straight carapace length, a tube with an outside diameter of 8 mm has been found suitable. For turtles over 55 cm, an outside tube diameter of 12 mm can be used. Insertion of the tube can be facilitated by lubrication with vegetable oil, and by placing a piece of electrical wire inside the tube to make it more rigid. This wire core is then withdrawn after the tube has reached the stomach. Once the tube is in position, retrieval of a sample can be enhanced by introducing a small quantity of sea water into the stomach before aspiration. It should be noted that difficulties with the insertion of the tube are more likely to be encountered with turtles larger than 70 cm. An earlier stomach sampling procedure for Hawaiian *Chelonia* employed the use of retractable forceps controlled through a small diameter flexible shaft (Balazs, unpublished). While this technique proved effective in many cases, greater success and efficiency has been achieved using the plastic tube. A method of determining the dietary components of crocodilians which also incorporates a plastic tube to sample stomach contents has been described by Taylor and Webb (1978).

A third method of sampling involves the examination of fecal pellets found washed ashore along the coastline bordering certain feeding pastures. Specific identifications have been made of benthic algae and, at times, invertebrates recovered in a relatively undigested state from such feces. Samples of the stomach contents of turtles captured in the same feeding pasture have closely resembled those obtained from the fecal pellets. This inefficient digestion in green turtles has not been previously reported and further investigations are being conducted of its scope and significance.

Discussion

Of the three methods described, recoveries of food samples from the mouth and the stomach have proven to be the most valuable. This is due to the fact that samples are derived from turtles of known size that can be identified by tagging and, therefore, are available for recapture and resampling at a future date. Individual recognition is not possible from fecal pellets, and only an estimation of the turtle's size can be made by measuring the diameter of the fecal pellet. The preliminary results of research on Hawaiian *Chelonia* using mouth and stomach sampling methods have recently been presented (Balazs, 1979).

Post-mortem examinations conducted on green turtles of different sizes salvaged from Hawaiian waters have indicated that the stomach is comprised of two separate compartments. The differentiation of these areas appears to become more pronounced as the size of the turtle increases. Use of the sampling tube results in the retrieval of food material from the first compartment. As in the esophagus, numerous soft papillae are located on the mucosa of this gastric area.

Green turtles basking ashore in the remote Northwestern Hawaiian Islands have on

occasion been observed to regurgitate into their mouth and subsequently reswallow the material. It is unknown, however, if this is due to a vomiting reflex or simply represents compression of the stomach caused by upward movement of the plastron from resting on land. The artificial induction of vomiting through the use of noninjurious drugs is well known for some animals (Borison and Wang, 1953). If green turtles are able to vomit, the development of such an emetic could provide an additional effective method for field sampling of dietary components.

Acknowledgements

This research was conducted with grants from the State of Hawaii, Office of the Marine Affairs Coordinator, and the University of Hawaii Sea Grant College Program (04-8-M01-178) contribution No. UNIHI-SEA-GRANT-JC-79-11. I am grateful to Dr. G. Causey Whittow and Dr. Leighton R. Taylor for reviewing a draft of this paper and making helpful suggestions.

EDWIN JAMES'S REPORT ON *BIPES* RECONSIDERED

About forty years ago the well-known herpetologist Edward H. Taylor (1938) expressed his conviction that a species of *Bipes* occurs in southeastern Arizona, at least in the Huachuca and Santa Catalina mountains. This opinion was based on oral reports made to him by a number of local people, none of whom were herpetologists. So far, Taylor's surmise has apparently never been verified, although Hobart M. Smith (1946) gave the suspected animal a tentative common name (Arizona worm lizard) and even tentatively mapped its probable range. Later on, Smith and Taylor (1950) went so far as to state flatly, without reservations, that the genus *Bipes* occurs in southeastern Arizona. This was a remarkable procedure considering the total lack of specimens from anywhere near Arizona in known herpetological collections, and the fact that no herpetologists claimed to have seen the animal in the field.

It seems even more remarkable in view of Taylor's summary dismissal, in his 1938 paper, of Edwin James's circumstantial account of bipes-like creatures observed and collected on June 27, 1820, in the South Platte Valley of present-day Nebraska or Colorado during Major S. H. Long's Expedition to the Rocky Mountains (James, 1823). The locality was probably on the south side of the South Platte River somewhere between the modern towns of Ogallala, Nebraska, and Julesburg, Colorado. In James's account we read: "We observed, in repeated instances, several individuals of a singular genus of reptiles (chirotes, Cuv.) which in form resemble short serpents, but are more closely allied to the lizards, by being furnished with two feet. They were so active, that it was not without some difficulty that we succeeded in obtaining a specimen. Of this (as was our uniform custom when any apparently new animal was presented) we immediately drew out a description. But as the specimen was unfortunately lost, and the description formed part of the zoological notes and observations which were carried off by our deserters, we are reduced to the necessity of merely indicating the probability of the existence of the chirotes lumbricoides of naturalists, within the territory of the United States."

The deliberate use of the old name "chirotes" in this account makes it virtually certain that an animal like that now known as *Bipes* was meant, and that the "two feet" were in front, not behind. We should keep in mind that we are here dealing with an account prepared by competent naturalists, not by laymen in the subject. Nevertheless, in his 1938 paper, Taylor states that this report "... has been given little credence. One wonders upon what animal such a report was based, or whether the account is fictitious." He cites Harlan (1827) to support his view that James's account was (and evidently ought to be) given little credence, but it appears to me that Harlan's remarks can just as well be interpreted to mean that he (Harlan) had made an oversight, in the absence of specimens, in not mentioning the *Chirotes* report in his original 1826 paper on the genera of North American reptiles. What Harlan said in 1827 was as follows: "In the Methodical Table of the North American Reptilia [*i.e.*, in is 1826 paper], we have omitted to notice a species of Chirotes, the existence of which in this country is indicated in Major Long's Expedition to the Rocky Mountains, vol. 1, p. 484." What exact meaning Harlan meant to convey must be left to the interpretation of the individual reader.

I do not think that James's account of *Chirotes* in the South Platte Valley in 1820 deserved the cavalier treatment which Taylor accorded it, and certainly not to the point of impugning the scientific integrity of Edwin James and his fellow scientists of Long's Expedition by raising the suspicion that the whole thing was "fictitious," as if they had perpetrated a hoax and palmed it off as genuine. The zoologist of the expedition was Thomas Say, who is known to have collaborated with James on the comprehensive report on Long's Expedition and who himself wrote most if not all of the zoological sections, even though his name does not appear on the title page as an author. Although Say is primarily remembered as an entomologist, he was also a very good general zoologist with competency in several vertebrate groups, including the Reptilia. His main interests in zoology were taxonomic, and as a matter of fact he was the original describer of a number of still-valid species and subspecies of American reptiles, including the following: *Crotaphytus collaris collaris, Cnemidophorus tessellatus, Lygosoma laterale, Natrix rigida, Natrix septemvittata, Thamnophis sauritus proximus, Thamnophis sirtalis parietalis, Carphophis amoenus amoenus, Coluber constrictor flaviventris, Masticophis flagellum testaceus, Elaphe obsoleta obsoleta,* and *Sistrurus catenatus tergeminus.* He also was the original describer of a western amphibian, *Bufo cognatus.* The toad and all but three of the twelve reptiles (the two water snakes and the eastern worm snake) were collected on Long's Expedition (Schmidt, 1953). These accomplishments alone would have made the reputation of any herpetologist.

There is every reason to suppose that Thomas Say closely examined the collected specimen of "chirotes" on that long-ago day in late June of 1820 in the remote, cactus-studded reaches of the South Platte Valley and then and there wrote out his usual careful description of the strange and unexpected creature. That the specimen was later lost is a great pity but not difficult to understand when we recall that the explorers were engaged in a long, hard, and dangerous journey, much of it through hostile and virtually unknown territory where mere survival was sometimes doubtful. The further loss, when the expedition had almost regained the safety of the frontier settlements, of nearly all the precious zoological notes so laboriously accumulated ever since the expedition headed westward from Council Bluffs on the Missouri River is an even greater pity. They were in saddlebags which were stolen by three deserters from the expedition's small military escort, and were

never recovered despite strenous efforts to do so.

Did a species of *Bipes*, or at any rate a *Bipes*-like reptile, occur in the South Platte Valley of southwestern Nebraska or northeastern Colorado in 1820? I do not see how we can seriously doubt it unless we simply disregard the explicit testimony of Long's Expedition. Whether the creature still occurs there is an altogether different matter in view of the great ecological changes which have taken place in the region since the advent of white settlement. On geographical grounds it might seem even less likely that *Bipes* ever existed in Nebraska or Colorado than in Arizona, which of course is much nearer the known range of the genus in southern Baja California and the southern Mexican mainland. But the Amphisbaenia is an ancient relict group of reptiles, a fact clearly evident from the scattered distribution over the globe of the known species, so it is not impossible that recent species of *Bipes* could have occupied, or might even still occupy, widely separated localities in the American West. It is at least arguable that the "chirotes" of Long's Expedition were members of a relict local population of an amphisbaenian species even then on the verge of extinction and now probably extinct.

Regional Society News

REGIONAL HERPETOLOGICAL PUBLICATIONS FIND PERMANENT HOME

It is now common knowledge that interesting and valuable herpetological information is being printed in numerous regional newsletters. The herpetological community now has a centralized location where regional works will be housed and where copies of particular articles can be secured. Ms. Nina J. Root, librarian at the American Museum of Natural History, has offered to be the recipient of all past, present and future newsletters, bulletins, and other publications of our various regional herpetological societies. The library at AMNH will catalogue all materials into their permanent collection, and will provide photo copies of articles at a nominal fee upon request. It is vitally important that all regional herpetological societies furnish the museum with complete volumes of past newsletters, and that the museum library be permanently placed on their mailing lists.

Send your regional newsletters, etc. to:

REGIONAL HERPETOLOGICAL SOCIETIES: A PERSPECTIVE

Regional herpetological societies are a relatively new phenomenon, although Chicago had a herpetologists' club in 1941. At least 40 regional societies occur in the United States, and others are to be found scattered throughout the world. Interest in herpetology has grown, but not as rapidly nor to the same extent that it has in ornithology. For the past decade, I have been actively associated with the Chicago Herpetological Society and have become acquainted with some other societies through correspondance and annual regional meetings. Some observations and thoughts on the function of regional societies and their relationship to professional herpetologists seem appropriate at this time. Some of the following is based on the history of the Chicago Herpetological Society and the specifics may be atypical of other societies.

Regional societies are made up of a diverse cross-section of the population: age varies from 12 years old to senior citizens; education ranges from people who did not finish the first eight grades to people with advanced degrees in a variety of disciplines; economic status is just as variable. The one common bond is an interest in amphibians and reptiles.

The present Chicago Herpetological Society was formed in 1966 when a reptile fancier placed a classified ad in a local newspaper. A small nucleus of interested people gathered, and within a short time the membership was nearing 100 people. By the late 1960's, the CHS meetings were a center for amphibian and reptile commerce. On the last Wednesday of each month, animals, such as Galapagos tortoises, South American coral snakes and crocodilians, could be viewed, bought, sold or traded. In the early 1970's, the animal trade was banned at CHS meetings. Predictions of the collapse of the organization proved unfounded. Members still buy, sell and trade animals, but not at the meetings and not on the scale of the late '60's. Few dangerous or endangered animals appear at meetings, or in members' collections, possibly from fear of peer pressure, but hopefully because fewer are available for private collections. Fifty to 100 members attend each monthly meeting to interact with others holding similar interests and to view the programs, which regularly feature professional herpetologists.

As regional societies evolve, they must go through a maturation process analogous to the one experienced by the CHS. Maturation may occur at different rates, but it is inevitable. Clearly, the maturing of a regional society is a time of turmoil, and the survival of the society is dependent upon the people available to fill leadership roles.

Kauffeld (1973) proposed a national organization of amateur herpetologists, suggesting that it be called the Holbrook Society and that it be modeled after the Audubon Society. The parallels between the amateur and professional in herpetology and ornithology are striking and interesting.

Although birders are supposedly a conservation-minded cult, Graham (1979) discusses problems caused by some birders' misguided enthusiasm. Graham's article "Case of the Ugly Birder" describes the mad rush of birders to Arizona's Chiricahua Mountains to observe, photograph and record the elegant trogon, *Trogon elegans*. Reptile collectors invade the same location each year to turn rocks and logs, probably the same ones that have been trampled by the birders, in search of an Arizona mountain kingsnake, *Lampropeltis pyromelana*. Certainly, these behaviors have homologous motivation, and both have negative affects on the organisms which are viewed with affection by the hunters. An article titled "Case of the Ugly Herper" would not be difficult to compose. Clearly, regional societies are the place to spread an environmental—conservation oriented ethic.

Graham noted that the American Birding Association (ABA) ". . . was formed in 1969 to promote the hobby of birding and the study of birds. . ." and to emphasize the pleasures of

the chase. Regional societies would do well to follow this approach. McCraine and Wilson (1979) have suggested that descriptions of new taxa not be published in regional society publications, a suggestion with which I completely agree. Regional publications should be used to inform members of current thinking, discoveries, and conservation efforts, but not as a replacement for already existing professional journals. The majority of regional society members are not interested in reading quantitative research or systematic revisions. They are, I believe, more interested in good quality natural history and husbandry articles. Regional and professional journals should fill two distinct niches, although at the present time there is some overlap.

Roger Tory Peterson has been quoted as saying that the ABA is "a healthy antidote to the academic snobbery of some professionals" (Graham, 1979). The extent to which this exists in herpetology is undetermined. While some professional herpetologists take an enthusiastic and active role in regional societies, others shun them. However, the relationship between the amateur and professional herpetologists can be viewed as protocooperation as defined by Odum (1959). Interaction is favorable to amateur and professional but the relationship has not yet evolved to the point of obligatory mutualism. Some professionals have done much to stimulate interest among amateurs. Indeed, how many Ph.D. herpetologists started in the amateur ranks? On the other side of the coin, it would be interesting to have statistics on the number of academic careers in herpetology influenced by amateurs. The role of the amateur has been important throughout the history of biological sciences. Where would modern biology be without the efforts of two talented amateurs named Darwin and Wallace? Therefore, who better to provide guidance and encouragement for regional societies than the local professionals.

Regional societies can be used for the betterment of herpetology. Mitchell (1979) has suggested using regional societies to gather phenological data, much in the same way population counts and migratory data are collected by the Audubon Society chapters. Collecting phenological data by regional societies would require organization, but it would provide a massive data base for life history studies. It would also provide an excellent direction for the field oriented amateur, and could be used to reinforce a conservation ethic. Applegarth (1975) has suggested a herpetological life list similar to the one used by birders. In order for a specimen to qualify for the list, it cannot be removed from the wild. The SSAR's Standard Common and Scientific Names for North American Amphibians and Reptiles could be promoted as the reference list for such activities.

The future of amateur herpetology is bright; new regional societies are organizing. Although a few disband, others become increasingly stable. The Chicago Herpetological Society had over 500 members at the end of 1979. Birding tours have become a big business in recent years. How long will it be before travel agencies offer tours for the herpetologist? The CHS has had organized field trips for several years. 1980 will see a CHS organized field trip to Australia, specifically aimed at observing and photographing herptiles.

A loose network of communication between regional societies and the SSAR Liaison Committee has been established. Unfortunately, obtaining responses from some regional societies has been difficult. The Committee can use your assistance. If you are in contact with members of a regional society listed in HR 10(4):110-111, an inquiry into who handles the correspondance with the Liaison Committee could prove productive. Should you know of a regional society that is not on the list, I ask that you contact the Committee Chairman. The Liaison Committee realizes that all regional societies may not be interested in annual meetings or grant programs. However, as societies mature and grow, interests change.

Dear Dr. Goyen:

The Society for the Study of Amphibians and Reptiles (SSAR) is an international organization with over 1,800 members. It is deeply concerned with the petition prepared by the National Turtle Farmers and Shippers Association (NTFSA) to lift the ban on domestic

HERPETOLOGICAL SKELETONS SKULLS

Prepared for educational and display needs.

Over 1000 specimens in stock. From 2 in. tree frog to 7 ft. monitor lizard and 16 ft. python.

We welcome your requests and inquiries.

For illustrated pricelist write to:

Herp Osteo-Specimens

3919 A West Magnolia Blvd.
Burbank, California 91505

(note our new address)

turtle sales (petition enclosed). Problems involved in the petition are as follows:

1. Turtles may not be able to survive in the bubble without food for the length of time it takes the animal to reach the consumer from the turtle farm. The petition states that after hatching, baby turtles can live on their yolk for one year, but there were no data to substantiate this. Serious doubt exists that the animals could live this long without food.
2. Liquid wastes may accumulate in the bubbles, killing the turtles before they reach the consumer.
3. Standards of shipping temperatures should be established. The bubbles should be kept from direct sunlight, as the greenhouse effect would cause temperatures to raise drastically.
4. Resistant strains of *Salmonella* and *Arizona* may develop from the treatment of eggs described in the enclosure. Regular checks by the Food and Drug Administration for *Salmonella* and *Arizona* of turtles being sold should be made. Concern also exists relevant to possible long term deleterious effects on turtles from the gentamicin egg treatment.
5. Turtle eggs should not be collected from the wild, as this may damage wild populations. Turtles sold as pets should be those that were a result of captive breeding.
6. The chance that a child will contract *Salmonella* or *Arizona* from a baby turtle will always exist, even if the turtle is free of these organisms when purchased. The turtle may acquire and foster the disease once in the home.
7. If all bacteria are killed in the turtle's bubble environment, questions arise as to the animal's ability to properly digest food.

In considering the above seven points, the SSAR feels that the enclosed proposal to lift the ban on domestic turtle sales is not feasible. From the information available, it appears that implementing the NTFSA plan would result in the inhumane treatment and death of thousands of baby turtles.

Sincerely,

Hugh Quinn
Chairperson
SSAR Legislative Alert Committee ●

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Dept. of Herpetology, Fort Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, TX 76110.

EQUATING FOOD AMOUNT FOR LABORATORY REARED TURTLES

We have been observing young snapping turtles (*Chelydra s. serpentina*) in our laboratory for several years. One phenomenon of interest is the differential growth rates among the turtles. Since growth depends on temperature and amount of food, we sought to at least record, if not control, variation in these factors. At first, the amount of food (beef liver) given to each turtle was quite variable because we simply tried to cut small similar-sized chunks. Mr. Denis Hancock, a colleague, suggested a simple technique which has given us much more precision in food amount. We now use a modified syringe to equalize the amounts of food given to each turtle.

The 12cc plastic syringe is prepared by cutting off the end which accommodates the needle. This provides a continuous cylinder with holes on both ends. Liver is cut into strips about the diameter of the cylinder and is sprinkled with vitamin and mineral supplements before being inserted into the syringe. A plunger at both ends is used to force out excess air and this preparation is then frozen.

For feeding, the frozen liver is pushed from the syringe and cut with a single-edge razor blade at .2cc intervals. These thin circles rapidly thaw and provide fairly equivalent amounts of food for each of the turtles which are housed separately. The mean weight of a sample of 25 slices which were air dried for three hours before weighing was .108g (s.d. = .014g).

This simple and inexpensive technique for equating food amounts could be easily adapted to different situations. Larger syringes could be used for larger pieces of food and other foods could be substituted for the liver.

COPROPHAGY IN *THAMNOPHIS S. SIRTALIS*

Certain reptiles have been known to ingest their own fecal material, notably tortoises of the family *Testudinidae* (Grzimek, 1975) and *Dipsosaurus* (Stebbins, 1966). However, I have found no reports of this behavior in snakes.

A female *Thamnophis s. sirtalis* collected in 1974 at Sargent, Matagorda County, Texas has been in the reserve section of the Houston Zoo for four years. The snake is 66.6 cm SV, 72.4 total length and weighs 185.5 gm. It was caged in an all-glass 16 liter aquarium measuring 36 x 21.5 x 26 cm. Light was provided by a Westinghouse fluorescent 40 watt tube 2 m. above the cage. Water was available at all times, and the ophidian was fed a half or full grown mouse each week.

In the early part of October 1978, the snake was observed ingesting its feces immediately after defecation. The fecal matter appeared to consist primarily of mouse hairs. The snake has not since been observed repeating this behavior.

ACKNOWLEDGEMENTS

I am grateful to Hugh R. Quinn and John E. Werler for reviewing this manuscript and to the Herpetological Staff of the Houston Zoo for their assistance.

TO ORDER:

To SSAR members, *if ordered before 1 August 1980* . . . . . ☐ $10 paperbound* ☐ $14 clothbound

To non-members; Institutions; all orders after 1 August . ☐ $20 paperbound* ☐ $24 clothbound

**Persons wishing to change orders to clothbound copies can remit an additional payment of $4.*

Prices include packing and shipping world-wide. Address orders to Dr. Henri C. Seibert, Department of Zoology, Ohio University, Athens, Ohio 45701, U.S.A. Receipt sent on request only. Mark here ☐ if you wish to have a complete pricelist of SSAR publications including the *Journal of Herpetology, Facsimile Reprints in Herpetology, Herpetological Review, Herpetological Circulars, Catalogue of American Amphibians and Reptiles,* and the publications of The Ohio Herpetological Society.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

THE REPRODUCTIVE BIOLOGY OF *BOMBINA ORIENTALIS*, WITH NOTES ON CARE

The leopard frog, *Rana pipiens*, has been an important resource for developmental studies for a number of years. Recently, however, use of this organism has become restricted; the supply of breeding animals has declined, and the quality of eggs has deteriorated (Gibbs, Nace, and Emmons, 1971; Anonymous, 1973). This situation has led us to search for alternative laboratory amphibians for use in developmental studies. Workers in several laboratories have suggested that *Bombina orientalis*, the oriental fire-bellied toad, may be a superior research animal (Nace and Ryuzaki, personal communication; Kawamura, Nishioka, and Ueda, 1972). If this animal is to be used for developmental studies it is imperative that its reproductive biology be well understood. As a preliminary to nuclear transplantation studies, we have developed reliable methods for controlling ovulation.

Sexually mature male and female toads were obtained from the Amphibian Facility, University of Michigan. The animals were kept in covered plastic boxes (about 25 cm by 34 cm by 8 cm deep) containing dechlorinated tap water; up to 9 animals were kept in each box. The boxes were tilted, providing a dry surface at one end and a shallow pool of water at the other end. Wastes accumulate in the water, as does a toxin produced by the toads, so it is important that the water be changed regularly; we changed the water daily or every other day. The animals readily eat living crickets, earthworms, and mealworms. Additionally, we found that it was easy to train the animals to accept pieces of beef liver from forceps; liver made up the bulk of the diet of our toads, which were fed three times a week.

Standard amphibian methods may be used to induce ovulation (Rugh, 1962). We successfully used injection of anuran pituitary glands into the abdominal cavity and injection of human chorionic gonadotropin (HCG) into either the abdominal cavity or the dorsal lymph sac. Dorsal subcutaneous injection of HCG (Ayerst or Sigma) proved to be the most reliable procedure. From April through October a dose of 125 international units (iu) was sufficient to induce ovulation; doses of about 250 iu were required during the remainder of the year. Males were induced to couple with injected females by similar hormone injections. Dosages for males were approximately one-half those required for females. Injected pairs were mated in large glass bowls containing about one cm dechlorinated tap water; the bowls were kept in the dark during mating, with mating typically done at room temperature. Onset of egg release varied, beginning as soon as 10 hours after injection or as late as 18 hours after injection; on rare occasions, eggs were not released until more than 20 hours after injection. Generally, the interval between injection and onset of egg release was temperature dependent; at 25°C the time was usually about 10 hours, while at 18°C the time was usually about 18 hours. Egg release continued for up to 10 hours after onset.

Fertilized eggs were transferred to finger bowls, where they were reared in 10% Barth's solution X (Barth and Barth, 1959) or in dechlorinated tap water. While tadpoles can be reared to metamorphosis in finger bowls, we found that optimal growth resulted when tadpoles were reared in aquaria containing aerated tap water and aquatic plants. Tadpoles were fed boiled romaine lettuce; additionally they grazed on the algal growth lining the aquaria walls. It was not necessary to change the water in aquaria during the larval period; water was changed daily for tadpoles reared in finger bowls.

At the onset of metamorphosis, the animals were removed from the aquaria and were placed in plastic boxes similar to those used for the adults. For the first several weeks after metamorphosis, the juveniles were fed adult *Drosophila melanogaster*; the toads were then taught to accept liver from forceps, and their diet was gradually shifted to that characteristic of the adults. Animals were reared to sexual maturity in approximately one year.

For many experiments it is desirable to have fertilized eggs available at a designated time. The method of mating discussed above does not insure this, since there is a great deal of variability in the interval between hormone injection and the onset of egg release. Eggs can be artificially inseminated using standard procedures for amphibians (Rugh, 1962), but this requires sacrifice of the male. Because of a population of limited size we developed a procedure that allows close control over the onset of egg release. In the absence of the stimulus of a clasping male a hormone-injected female kept at 18°C will begin to shed eggs spontaneously about 18 hours after injection. We found that if the male and female were injected and kept apart for about 16 hours at 18°C, then the female was "primed" for egg release. Placing the male and female together at that time led to immediate amplexus. Egg release consistently began within one hour of mating. This close control made it possible to perform experiments with freshly fertilized eggs at designated times.

We also tried other means of controlling egg release in *Bombina*. Spontaneous egg release can be prevented in ovulated *R. pipiens* by maintaining the females at 4°C (Rugh, 1962); a female will retain viable eggs for several days under these conditions. In several instances, *B. orientalis* females were placed at 4°C at the onset of spontaneous egg release. This led to immediate cessation of egg shedding. Eggs were again released after the females were returned to room temperature. However, even after as short a period as 2 hours at 4°C, most of the subsequently released eggs were inviable. Therefore it is apparent that cold temperature may not be used to control egg release in *B. orientalis*.

In our nuclear transplantation studies, it was necessary to obtain unfertilized eggs at specific times. The eggs of *B. orientalis* are considerably larger than those of *R. pipiens* (2.0 to 2.5 mm in diameter as opposed to 1.0 to 1.5 mm in diameter), though *B. orientalis* is much smaller than *R. pipiens*. Further, the *Bombina* eggs are more fragile than the *Rana* eggs. Consequently, eggs cannot be stripped from *B. orientalis* females using the procedures developed for *R. pipiens* (Rugh, 1962). Stripping of *B. orientalis* eggs in this fashion leads to deformation and damage, as is indicated by disruption of the egg pigment pattern. However, it is possible to obtain undamaged eggs from hormone-injected females. A female toad, injected 16 hours earlier and kept at 18°C, was placed in a dish with shallow water. The toad was then grasped immediately anterior to the pelvic girdle with the thumb and forefinger. A steady but gentle pressure was applied for several minutes; the female responded to this pressure and began to lay eggs. The eggs were propelled along the oviduct by the toad's own muscular contractions rather than by external pressure, and the eggs were shed undamaged. The procedure apparently mimics natural amplexus. The viability of eggs obtained in this manner was indicated by their ability to be fertilized by a sperm suspension.

Our studies indicate that *B. orientalis* is indeed an ideal laboratory amphibian. The animal is hardy and easy to care for. Eggs may be obtained throughout the year. Animals can be bred repeatedly. An average female will produce 100 to 200 eggs per ovulation if the interval between ovulations is 6 weeks; if the interval is 3 months, the number of eggs expected is 200 to 400. The percentage of fertilization remains consistently high (about 95%) if the females are kept on a regular breeding schedule. We usually mated the females once every 6 weeks to 2 months and the males once every month; the males have been used as often as once a week with good results. The eggs are large and can be experimentally manipulated (Ellinger and Carlson, 1978). We feel *Bombina* has the potential to be an outstanding laboratory resource, one which possesses desirable traits not found in some commonly used anurans. In many ways, its characteristics resemble those of *Ambystoma mexicanum*, which is becoming a very popular organism for developmental and genetic studies (Malacinski and Brothers, 1974). The procedures discussed above provide a reliable approach for exploiting the reproductive biology of *Bombina* in the laboratory.

specimen are labeled with the correct Latin name.

No one decries the incorrect identifications in "picture books" more than myself. There are surprisingly few obvious misidentifications in this book (at least among the species with which I am familiar)—and I was quite dismayed to note that one of them was due in part to me. Anyone wishing to obtain a slide of *Ambystoma laterale* (collected near Chicago, Ill.) can write to me and I will put one in the mail promptly.

NEWSNOTES

BOTANY—NATURAL HISTORY OF PANAMA

A symposium to signal completion of the Flora of Panama will be held 14-17 April. Sessions will cover the physical setting, archaeology, vegetation, flora, fauna and demography of Panama and nearby countries, as well as other natural history related topics. A number of herpetology papers will be presented. Both invited and contributed papers will be given, and simultaneous Spanish/English translation will be provided. For further information, contact:

Prof. Mireya D. Correa A.
Escuela de Sciencias Naturales y Foramacia
Estaseta Universitaria
Univ. of Panama
Republic of Panama

Information on financial assistance is available from:

W. G. D'Arcy
Missouri Botanical Garden
2315 Tower Grove Ave.
St. Louis, MO 63110

AUDUBON GUIDE ERRATUM

I wish to express my sincere apologies to the herpetological community for the misrepresentation which appeared in the recently-published *Audubon Society Field Guide to North American Reptiles and Amphibians*. As many have undoubtedly noticed, Plate 58 is an illustration of *Ambystoma jeffersonianum* rather than *A. laterale*. The specimen was collected in Jessamine County, Kentucky in October of 1977 and was photographed as a representative adult in non-breeding condition. I am not sure at this time how the slide was labeled (it has not been returned from the publisher), but others in my files of the same

AWARDS FOR STUDY AT ANSP

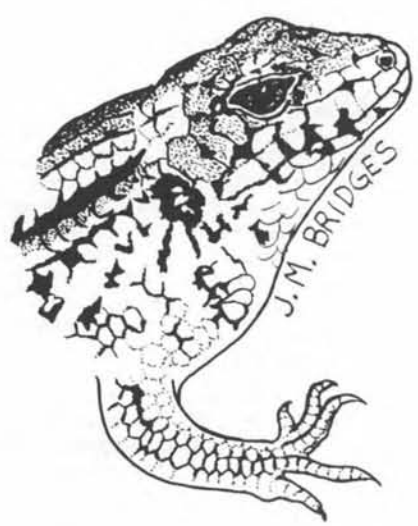
The Academy of Natural Sciences of Philadelphia, through its Jessup and McHenry funds, makes available each year a limited number of awards to support students pursuing natural history studies at the Academy. Awards usually include a stipend to defray living expenses, and support for travel to and from the Academy. Current application deadlines are 1 April and 1 October 1980. Further information may be obtained by writing to: Chairman, Jessup-McHenry Award Committee, Academy of Natural Sciences of Philadelphia, 19th and the Parkway, Philadelphia, Pennsylvania 19103.

COLUBRID SNAKEBITE EFFECTS—INFORMATION REQUESTED

I am compiling worldwide records on colubrid snakebite effects in prey, experimental animals, and humans for a second review article. Any information, particularly unpublished observations and citations for papers in journals not widely circulated, would be appreciated. Please contact Donald M. McKinstry, Department of Biology, Behrend College, The Pennsylvania State University, Erie, Pennsylvania 16563.

BUFO MARINUS PUBLICATIONS

Bufo marinus is one of the most widely distributed of amphibians. The species is naturally found from southern Texas to central Brazil. The toad has become a popular subject for introduction to new locations, starting in the early 1800's into the Carribean islands. In the 1900's, the species was carried into the Pacific via Hawaii. At present the toad is rapidly expanding its range in continental Australia (at about 8% per annum). Australian interest in the species is large since it is considered to be a minor pest. In order to predict the eventual range of the species on the continent, we have begun compiling the range records for both natural and introduced populations. The records include both museum specimens and survey sightings (especially in Australia). We are publishing these records to provide a baseline account of the distribution to serve as a basis for future work on the species (particularly an analysis of its tolerance to climatic variables). The publications will be in 4 parts under the general title "The distributional records of the marine toad, *Bufo marinus*": Part 1, Australia; Part 2, the Pacific islands; Part 3, The Carribean and Florida, USA; and Part. 4, Mainland Latin America. The first part will be available in early 1980 and can be obtained, gratis, from:



School Administrator
School of Australian Environmental Studies
Griffith University
Nathan, (Brisbane), 4111, Australia.

AMPHIBIAN PHYSIOLOGY SYMPOSIUM

June 24-25, 1980 at University of California (Davis). Sessions include Water Relations, Thermoregulation, and Aerobic/Anaerobic metabolism. For more info, contact: Robert C. Drewes, Dept. of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, CA 94118.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The *standard format* for a geographic distribution record is:

Scientific name (common name) as it appears in *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (Collins, Huheey, Knight and Smith, 1978). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalog number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, Univ. of Kansas, Lawrence, KS 66045. Short manuscripts are only acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new distribution records appearing in *Herpetological Review* is: Jones, J. 1977. Geographic distribution: *Rana pipiens*. SSAR Herp. Review 8(1): 1.

GYMNOPHIONA

SCOLECOMORPHUS VITTATUS (African Caecilian). Kilimanjaro Region, Pare District, North Pare Mountains, Kifula, Ugweno. 13 December 1976. C. A. Msuya. Verified by B. Clarke, British Museum (Natural History), in collection of K. M. Howell (KMH 311). Duplicates collected earlier at same locality in December, 1975 deposited in University of Dar es Salaam Vertebrate Collection (UDSM 683-684). Species known previously from Usambara and Magrotto (120 km southeast present locality) and Uluguru Mountains (360 km south of present locality) (Loveridge, 1957, Bull. Mus. Comp. Zool. 117(2):306).

STEREOCHILUS MARGINATUS (Many-lined Salamander). USA: GEORGIA: Atkinson Co: 4.2 km S Pearson on U. S. Rt. 221 (1 km S jct. U.S. Rts. 221 and 441). 26 October 1978. F. G. Thompson, H. W. Campbell and S. P. Christman. Verified by S. P. Christman. Florida State Museum, Gainesville (VF 45279). Northwestern extension of range of 73 km and first record for Atkinson County (Christman and Kochman, 1975, Florida Sci. 38(3): 139-141).

Submitted by **HOWARD W. CAMPBELL, STEVEN P. CHRISTMAN,** and **FREDRICK G. THOMPSON,** National Fish and Wildlife Laboratory, 412 N.E. 16th Avenue, and Florida State Museum, University of Florida, both in Gainesville, Florida 32601. ●

ANURA

GASTROPHRYNE CAROLINENSIS (Eastern Narrowmouth Toad). USA: ARKANSAS: Pope Co: 6.4 km SE Dardanelle on Holla Bend National Wildlife Refuge. 2 June 1976. B. Shackleford. Arkansas Tech. Univ. uncat (field number GDT 88); Yell Co: 4.02 km S Dardanelle on Rt. 155. 16 May 1976. D. Carroll. Arkansas Tech. Univ. uncat (field number GDT 68). New county records for west-central Arkansas (Nelson, 1972, Cat. Amer. Amph. Rept. 120.1-120.4).

Submitted by **GLYN TURNIPSEED,** Department of Biology, Arkansas Tech University, Russellville, Arkansas 72801. ●

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: COLORADO: Baca Co: 37 km S and 8 km W Pritchett. 29 May 1979. G. Hammerson and L. Livo. Univ. Colorado Mus., Boulder (UC 51967-51968); 36.2 km S and 19.3 km W Pritchett. 18 July 1979. G. Hammerson (UC 51966); 37.8 km S and 1.6 km E Pritchett. 18 July 1979. G. Hammerson (UC 51965). 29.8 km S and 16.1 km W Pritchett. 1 August 1979. G. Hammerson (UC 51964). Verified by H. M. Smith. First records for the state. Extension of 30 km NW of Collins' record (1979, Herp. Rev. 10(3):101) of major westward range extension in northern portion of range. Specimens of 29 May were found under rocks on a hillside near a stock

pond; all others were collected from choruses in rain pools or stock ponds.

TESTUDINES

CLEMMYS MUHLENBERGI (Bog Turtle). USA: GEORGIA: Union Co: Chattahoochee National Forest. 10.5 km SSE Blairsville. 8 May 1979. P. E. Hale and M. J. Harris. Verified by E. E. Provost, Zoology Department, University of Georgia. Univ. Ga. Nat. Hist. Mus. (UGA 1541-series of four color photographs). Total of 5 captures made in same vicinity from 8 May 1979 to 16 July 1979; at least three different individuals, all released. First record for the state and extends the range at least 22.5 km S from the southern boundary of Clay County, North Carolina; this bordering county has at least two records, neither of which gives exact location data (Brimley, 1922, Copeia, No. 107:48; Nemuras, 1974, Wildl. North Carolina, 38(2):13-15).

Submitted by **PHILIP E. HALE** and **MICHAEL J. HARRIS,** Institute of Natural Resources and School of Forest Resources, University of Georgia, Athens, Georgia 30602. ●

EMYDOIDEA BLANDINGI (Blanding's Turtle). CANADA: ONTARIO: Frontenac Co: Marsh on NW shore of Grenadier Island. 12 October 1978. B. Collins. Collection of P. J. Petokas, PJP 141 (shell only). Verified by M. M. Alexander. Previous records of the Blanding's turtle from islands in the International section of the St. Lawrence River include only those for Wellesley Island, USA (Werner, 1959, Copeia 1959(2): 170-172; Petokas and Alexander, 1978, SSAR Herp. Rev. 9(3):107) and Niagara Island, Canada (Toner, 1936, Copeia 1936(4): 236-237). This species has been observed to nest on Grenadier Island and is reported to be common in the marshes of the NW shore (B. Collins, pers. comm.).

Submitted by **PETER J. PETOKAS,** U. S. Fish and Wildlife Service, 100 Grange Place, Cortland, New York 13045 and **MAURICE M. ALEXANDER,** Department of Environmental and Forest Biology, SUNY College of Environmental Science and Forestry, Syracuse, New York 13210. ●

KINOSTERNON FLAVESCENS SPOONERI (Illinois Mud Turtle). USA: IOWA: Lee Co: 5 km south of Montrose, 200 m west of Mississippi River. 18 June 1979. J. Millmeyer. Verified by R. Feuer and J. R. Jordan. Released after identification. New county record and extends range southward into Missouri. Captured crossing sandy farm road. Specimen was photographed, measured and the first marginal laminae was permanently marked by notching. (Brown, L. and Moll, D., 1979. Milwaukee Public Museum, Special Publ. No. 3).

Submitted by **J. RICHARD JORDAN**, Department of Wildlife and Fisheries Sciences, Texas A & M University, College Station, Texas 77843. ●

TRIONYX SPINIFERUS ASPERUS (Gulf Coast Spiny Softshell). USA: GEORGIA: Charlton Co: St. Marys River at Ga. Rt. 23; SE ¼ sec. 31, T1S, R22E; 4 Oct. 1979; H. W. Campbell, S. P. Christman, and FLORIDA: Nassau Co., St. Marys River, SW ¼ sec. 13, T1N, R23E; 20 Oct. 1979; S. L. Christman, S. P. Christman. Verified by Howard I. Kochman. Florida State Museum, UF 45477 and UF 45478, respectively. First records for the St. Marys River System and first records for Charlton Co., Georgia and Nassau Co., Florida. Southern range extension of approximately 125 km from previous southernmost known locality on the Atlantic Coast, the Altamaha River (Webb, 1962. Univ. Kansas Pub. Mus. Nat. Hist. 13 (10): 429-611; Webb, 1973. Cat. American Amphibs. Repts., pp. 140.1-140.4). The species is now known to occur in all major coastal rivers from the Pee Dee in South Carolina to the Rio Purificacion in Tamaulipas except for a gap which includes the Ochlockonee, Suwannee, and St. Johns rivers in Florida.

LACERTILIA

EUMECES FASCIATUS (Five-lined Skink). USA: NEW YORK: Warren Co: 1.6 km WSW Sabbath Day Point, Bloomer Mountain. 12 and 26 May 1979. W. S. Brown and D. W. Pyle. Verified by R. G. Zweifel. Amer. Mus. Nat. Hist. (AMNH 118707) adult ♀; (AMNH 118708-118709) adult♂♂. Collected on south-facing slope in open talus rock deposits in mixed deciduous woodland, elev. *ca.* 200 m (♂, ♀) and in woodland on south-facing slope at *ca.* 400 m (♂). Two additional ♂♂ observed 21 May 1979 by Nancy L. Martin 1.6 km SW Sabbath Day Point, Warren County, New York, near Deer Leap on Tongue Mountain in talus rocks, elev. *ca.* 100 m. First records for county and for west side of Lake George. Extends range in northeastern New York 9.8 km SSW of Camp Sagamore, Washington County (Cornell Univ. 4052: Hamilton, 1947, Copeia 1947: 64) and 13.5 km SW of Putnam Station, Washington County (AMNH 87047), both prior known localities on east side of Lake George. In addition to the lake barrier between the Warren and Washington County localities in northeastern New York, a considerable hiatus (*ca.* 240 km) in range exists between the northeastern localities and known southeastern New York localities (Orange, Rockland, and Westchester counties - 7 specimens AMNH; Sullivan and Dutchess counties - range map in M. M. Stewart and J. Rossi, in press).

Submitted by **WILLIAM S. BROWN** and **DONALD W. PYLE,** Department of Biology, Skidmore College, Saratoga Springs, New York 12866. ●

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). USA: ALABAMA: Mobile Co: Dauphin Island, on Dauphin Island Sea Lab property at extreme eastern end of the island. 15 October 1978. J. J. Dindo. Verified by W. A. Cox, Samford University. Specimen was photographed and released. Color slides of the specimen are on file in the Vertebrate Museum, Biology Department, University of Alabama in Birmingham. First record for county and coastal Alabama and second for state (Mount, 1975, The reptiles and amphibians of Alabama, Auburn U. Press).

Submitted by **KEN R. MARION** and **JOHN J. DINDO**, Biology Department, University of Alabama in Birmingham, Birmingham, Alabama 35294. ●

SERPENTES

CARPHOPHIS AMOENUS VERMIS (Western Worm Snake). USA: ARKANSAS: Drew Co: 11.3 km N Monticello on US Rt. 81. 29 September 1976. C.R. Tumlison. Verified by E. J. Bacon. Private collection of C. R. Tumlison

(#60). 8 km S Monticello (S19, T13S, R7W). 15 April 1977. R. W. Wiley. Verified by E. J. Bacon. University of Arkansas at Monticello Collection of Vertebrates (UAM 1505-1506). First specimens reported from SE Arkansas, extends known range *ca.* 150 km SE from the western area of the state (Dowling, 1957. Univ. Arkansas Mus. Occas. Papers, No. 3).

Submitted by **C. R. TUMLISON** and **R. W. WILEY,** Department of Biology, University of Arkansas, Monticello, Arkansas 71655. ●

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). USA: ARKANSAS: Cross Co: Village Creek State Park, T7N, R4E, Sec. 30. 16 April 1979. J. A. Huggins. Verified by W. W. Byrd and V. R. McDaniel. Arkansas State University Herpetol. Mus. (ASUHM #3749). First record for the county and extends the published range *ca.* 151 km SE of previous record from Lawrence County (Dellinger, S. C., and J. D. Black. 1938. Occ. Pap. U. Ark. Mus. (1): 1-47). Additional living individuals encountered; it appears this snake has expanded its range east from NW Arkansas localities and beyond the reported zone of intergradation with *Nerodia e. erythrogaster* (Dowling, H. G. 1957. Occ. Pap. U. Ark. Mus. 3: 1-51; Conant, R. 1975).

Submitted by **CHRIS T. McALLISTER,** Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467. ●

DISTRIBUTION OF THE TAILED FROG, *ASCAPHUS TRUEI* STEJNEGER, IN SEVERAL DRAINAGES IN NORTHCENTRAL IDAHO

Ascaphus truei is a representative of a monotypic North American genus of frogs commonly referred to as the tailed frog. This entirely aquatic species is known from northern California, the coast range of Oregon, the Cascade Mountains of Oregon, Washington and British Columbia, the Olympic Peninsula of Washington and in several mountainous areas in western Montana and northern Idaho (Franz and Lee 1970; Metter 1964, 1968). Although works on the general distributions of *Ascaphus* are available (Metter 1968), little work on the specific distribution of this species in Idaho has been undertaken. The area included in our study was Idaho north of the Salmon River and south of the Coeur d'Alene River. Metter (1969) reported several occurrences within this area but did not specify occurrence within individual drainages.

Our study took place in several phases from 1967 to 1974. Extensive collections were made on the Clearwater, Palouse, and Coeur d'Alene Rivers. Supplemental collections were made in the St. Joe and St. Maries drainages. Most collections were made with backpack electrofishing units, using the technique outlined for collecting bottom fishes by Maughan (1972).

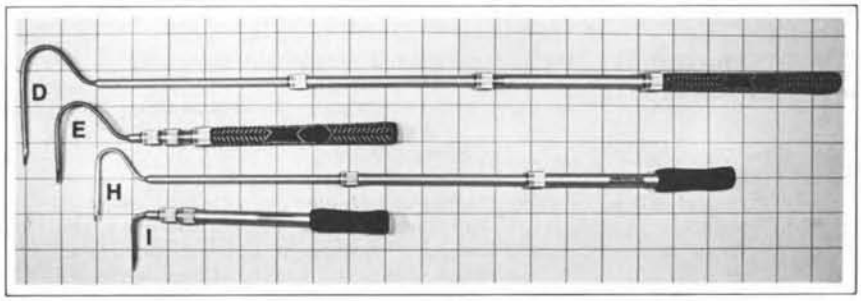
Tailed frogs were taken from 27 locations on the Clearwater River, 9 locations on the Coeur d'Alene River, 8 locations on the Palouse River, 7 locations in the St. Joe River and 2 locations on the St. Maries River (Figure 1). In addition, Metter (1978, personal communication) has taken *Ascaphus* from tributaries of Moose Creek and the Little North Fork Clearwater where we did not collect the species and from additional locations on the Lochsa ("Essentially all the small feeders to the Lochsa from ± 10 miles above its juncture with the Selway") and Palouse ("A small tributary coming off N. side of Moscow Mountain").

A. truei was widespread but spottedly distributed throughout the headwater areas of the streams sampled. However, *A. truei* was not found in all streams sampled. The spotty distribution may have resulted from previous local climatic conditions associated with glacial advance and retreat (Franz and Lee 1970) or from sampling bias, or from some unknown ecological factor associated with elevation. Virtually all populations encountered were above the 975 m elevation (3200 ft). Explanations for the restriction were not readily apparent.

Franz and Lee (1970) speculated that similar spotted distributions of *A. truei* in the flathead drainage in Montana resulted from refugial occupation during the Cordelleran Ice Sheet followed by secondary reinvasion as the ice sheet retreated. Secondary localized exterpations followed reinvasion as the result of warming trends accompanied by droughts and intermitant stream flows. This

COLLAPSIBLE HANDLE HOOK

*Field & Cage Models



DESCRIPTION / PRICES:

A reliable locking mechanism has been acquired for our standard duty Field and Cage hooks. We are happy to offer it as an option in a 4 section configuration for models D or E, (length 19 - 46 inches) and for model G, (length 16 - 43 inches), rated to 10 pounds. **Price $30.00**

Cage hooks are available in a 3 section configuration for model H, (length 16 - 35 inches) and for model I, (length 14 - 33 inches). Cage hooks are available only with a short grip. **Price $22.00**

hypothesis does not appear applicable to northern Idaho because adjacent creeks with similar climatic histories differ in their ability to support populations of *A. truei*.

The Pacific giant salamander, *Dicamptodon ensatus*, has a distribution similar to that of *A. truei*. Savage (1952) hypothesized that the discontinuity in the distribution of *D. ensatus* in the northern Rockies was not a real phenomenon. Maughan et al. (1976) substantiated this hypothesis and concluded that sampling bias was the cause of much of the apparent discontinuity. Based on our data the apparent discontinuity in the distribution of *A. truei* likewise appears to be partially an artifact of sampling.

Maughan et al. (1976) hypothesized that *D. ensatus* might be found south as far as the Bear River Drainage and north across a northerly boreal connection between the Rockies and the Cascades in the area of Wells Gray Provincial Park in Central British Columbia. We now believe this hypothesis applies also to *A. truei*.

Notes On The Occurrence Of Introduced Turtles In Arizona

Recently, Smith and Kohler (1968, Trans. Kansas Acad. Sci. 80:1-24) published a list of introduced amphibians and reptiles in the United States and Canada. The list indicates that only one species of turtle (*Trionyx spiniferus emoryi*) has been introduced to the state. In this paper I discuss five additional species or subspecies introduced to Arizona. Terminology for the status of the introduced forms follows that of Smith and Kohler. They define "endemic" as any species whose range enters into the political boundaries of the United States.

1 - Endemic Breeding Population Now In Existence (species that have successfully established breeding populations). To my knowledge only *Chrysemys scripta elegans* falls into this category. It is abundant in the ponds at Papago Park, Phoenix, Maricopa County and in the Gila River 5 mi SW of Buckeye, Maricopa County. Both of these locations have breeding populations of turtles. *Chrysemys scripta elegans* has been introduced to the state through the sale of hatchlings in pet and variety stores. At Papago Park individuals of all sizes, from hatchlings to large adults have been collected, suggesting that a breeding population is present. In addition, abdominal palpation confirmed the presence of oviducal eggs in several females. One road killed female from the Buckeye locality contained several shelled oviducal eggs. In the area around Phoenix these turtles are active throughout the year. Due to the complex system of irrigation canals and channels and the close proximity of these canals to the ponds at Papago Park it is likely that the turtles will spread their range to include the entire Salt River Valley.

2 - Endemic Released (releases are of sufficient magnitude and/or in areas of such favorable habitat that the establishment of breeding populations must be considered at least possible).

Chrysemys picta dorsalis has been introduced to Quitoboquito Spring, Organ Pipe National Monument, Yuma County. One immature female was collected in the spring. Park officials informed me that several individuals had been released into Quitoboquito by tourists. Quitoboquito Spring is excellent habitat for turtles and already supports populations of *Kinosternon sonoriense* and *K. fla-*

vescens (both native to Arizona). It appears that once the introduced *C. p. dorsalis* reach reproductive maturity they will establish a breeding population. The impact of these introduced turtles on the native species of *Kinosternon* remains unknown.

Chrysemys picta belli has been reported from Rock Creek Canyon, Navajo County by Yarrow (1875, Rept. Geograph. Geol. W. 100th Med., Chap. IV:509-584). Presumably this was a native population that has since been extripated. Several specimens of *C. p. belli* have been collected from the Papago Park ponds. The habitat at the ponds is adequate for the establishment of a breeding population. It remains to be seen if the numbers of *C. p. belli* are sufficient to such a population.

3 - Waif (Introductions of single specimens or two or more specimens of one sex in any area). One species, *Chelydra serpentina*, clearly falls into this category. A single individual of *C. serpentina* was found in a torpid state in the deserted fish hatchery at Papago Park. It is doubtful that any other specimens have been released.

Chrysemys scripta scripta is between category 2 and 3. A few specimens of this form have been found in the Papago Park Ponds, but the establishment of a breeding population is highly unlikely due to the small number of them in relationships to *C. s. elegans*, which are abundant in the ponds.

CURRENT LITERATURE

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. When they have been submitted, addresses will be included. An address following a citation is that of the first author unless otherwise noted.

Amphibians and Reptiles of the Carolinas and Virginia

by Bernard S. Martof,
William M. Palmer,
Joseph R. Bailey, and
Julian R. Harrison III
Photographs by Jack Dermid

The first illustrated guide to the amphibians and reptiles of the Carolinas and Virginia. Here—in stunning color photographs and with up-to-date accounts—are the region's 159 species of frogs, snakes, turtles, salamanders, lizards, and alligator. Range maps indicate where each species is found.

Each species account is illustrated and includes comments on distinguishing features, distribution, habitat, and life history. The text describes the geography, vegetation, and climate of the entire area and outlines its herpetofaunal history. A listing of endangered species, an index, a glossary, and a list of useful references also are included.

5½ × 8½, approx. 230 pp., color illus., $14.95

Ordering Information: Individuals should send check or Visa/MC information to publisher. Library orders will be billed.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

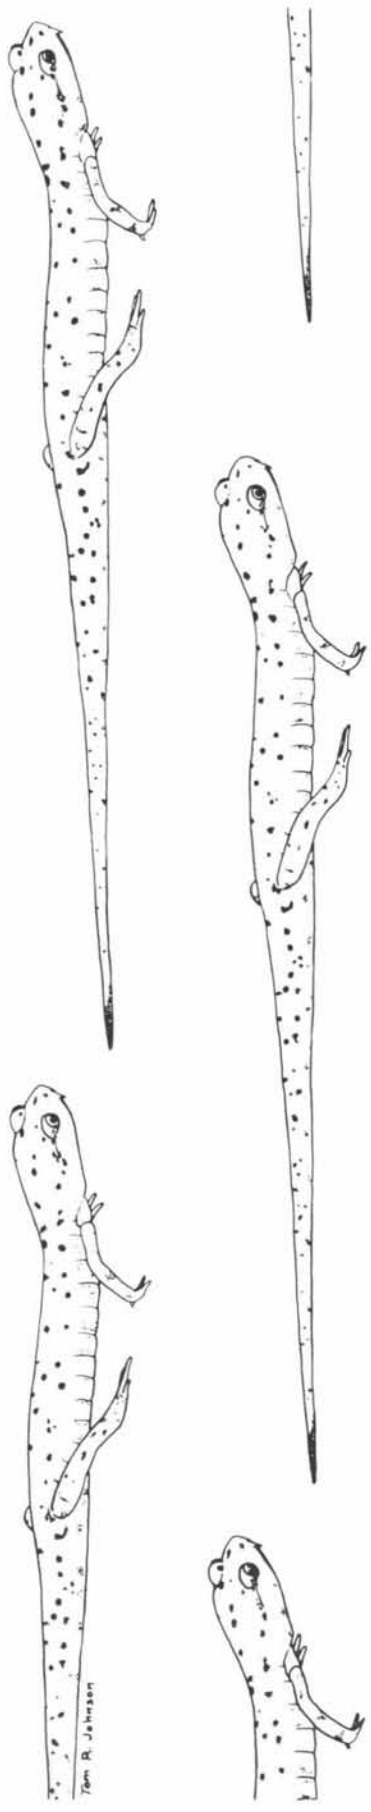
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars**, and several **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

Herp. Review—"Whither Thou Goest" or "Goest and Wither"?

Herpetological Review has reached the point of having so many "must be published in **HR**" items that adherence to our budget while striving to present issues with a "balanced" content (those sections of **HR** such as distribution, husbandry, society news, feature articles, reviews, and—by far the largest—Current Literature) has become virtually impossible. Several possible solutions exist, and at this point I feel it is appropriate to ask you, the membership, your feelings. We could reduce the coverage of much of what we now try to include in each issue, while keeping things you most desire. Hence, how highly do **you** value our present sections? Current Literature is, I know, valuable. So is Distribution. So is . . . The Board could increase dues by yet another small increment and **HR** readers could have all sections held as is. Would that be supported? Would you subscribe to a separate Current Literature publication (quarterly issues—*ca.* 5.00 per year)? This is not really that desirable an option as it creates bookkeeping headaches for the Treasurer and Publications Secretary. Should SSAR sell **Herp. Circulars** rather than distribute them to all members free, and use what's now the Circulars' budget to improve Current Literature within **Herp. Review** (we could typeset it and double our present coverage—but services cost money)?

Unlike the Journal, which has a fairly well defined and closed coverage, **HR**'s coverage is loosely defined. The SSAR constitution mandates that we have all SSAR business as a first priority, and beyond that it's largely editor's discretion. So, before the editor swings his axe, some feedback would be greatly appreciated. Please do it **now** as volume 11 will soon be with us.

George Pisani, Editor

HR EDITORIAL CHANGES

Beginning with volume 11(1):

Bern Tyron (Reptile Dept., Fort Worth Zoo, 2727 Zoological Park Drive, Fort Worth, TX 76110) will replace Jim Murphy as Herpetological Husbandry section editor;

Joseph T. Collins (address on inside front cover) will replace Joe Mitchell as Geographic Distribution section editor; the new RHS committee chairperson will replace Tom Johnson as Regional Societies section editor;

Joseph T. Collins will no longer co-edit **HR**.

Please direct all Section-oriented manuscripts to the appropriate section editor. It saves handling (and hence, publication) time on your manuscript. The editor sincerely thanks all outgoing section editors, as well as the manuscript reviewers for volume 10 for their generous gift of time to **HR**. Special thanks are extended to Joseph T. Collins for his help the past few years with **HR**.

1979 RECIPIENTS OF SSAR GRANTS-IN-HERPETOLOGY

In 1978 the SSAR Board of Directors approved a Grants-in-Herpetology program. Its purpose is to financially support projects in four areas in which traditional sources of funding are not appropriate. Eight hundred dollars were budgeted for the first year, and an additional $100 were received from the Northern Ohio Association of Herpetologists, permitting four grants of $225 each.

Twenty-four proposals were received, including ten for graduate student research, three for zoo research, five for conservation, and six for regional society projects. These were carefully considered by a committee consisting of C. Kenneth Dodd, Martin J. Rosenberg, John Behler, Stephen R. Edwards, and Harry W. Greene. The following winners were announced at the annual meeting in Knoxville: **Linda S. Ford** (graduate student research, University of Texas at Arlington), Interspecific relationships among cloud forest *Eleutherodactylus;* **John D. Groves** (zoo research, Philadelphia Zoological Garden), The food and feeding behavior of the emerald tree boa, *Corallus canina;* **Norman G. Reichenbach** (conservation, Ohio State University), Ecology and management of the prairie garter snake, *Thamnophis radix,* in Ohio; and **Wisconsin Herpetological Society** (regional herp societies), Production of filmstrips for herpetological education.

On behalf of the SSAR, I extend thanks to the committee members for their time and efforts, to the Northern Ohio Association of Herpetologists for their contribution, and to all those that submitted proposals. At least $1100 will be available for the 1980 grants, and we hope to receive a large number of quality proposals in each of the four areas (see News Notes in this issue for details). In the future, annual dues envelopes will include a space for donations, and we encourage members to financially contribute to the growth of the SSAR Grants-in-Herpetology program.

JUTERBOCK WINS 1979 SSAR KENNEDY AWARD

The 1979 SSAR Kennedy Award Committee has determined that the paper "Sexual Dimorphism and Maturity Characteristics of Three Species of *Desmognathus* (Amphibia, Urodela, Plethodontidae)," authored by J. Eric Juterbock, was the best student paper published in Volume 12 (1978) of the *Journal of Herpetology*. For his efforts the author was recognized and awarded a $100 check at the SSAR business meeting in Knoxville, Tennessee, on 15 August 1979.

I gratefully acknowledge the members of the 1979 Committee consisting of W. S. Brown, A. Channing, and J. D. Lynch for their efforts in this determination.

Michael V. Plummer, Chairperson
1979 Kennedy Award Committee ●

REPORT OF THE SSAR COMMITTEE ON COMMON AND SCIENTIFIC NAMES FOR 1979

This report is the second annual update prepared by the SSAR Committee on Common and Scientific Names for North American amphibians and reptiles (north of Mexico). This report (and future reports) is compiled to fulfill the charge to our committee to keep the herpetological community informed of published taxonomic shifts and new descriptions, and to propose or record new common names brought about by same. In addition, this second update permits us to record recent changes overlooked and not included in "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (Collins *et al.*, 1978).

The proposed changes and taxonomic shifts listed below are in order as they appear in our Common and Scientific Names list (Collins *et al.*, 1978).

PAGE 5, genus *Batrachoseps:* Marlow *et al.* (1979) described *Batrachoseps campi* with the common name "Inyo Mountains Salamander." This new species should be listed appropriately.

PAGE 8, genus *Plethodon:* Duncan and Highton (1979) described *Plethodon fourchensis* with the common name "Fourche Mountain Salamander." This new species should be listed appropriately.

PAGE 8, line 11: Guttman *et al.* (1978) proposed that *Plethodon longicrus* be placed in the synonymy of *Plethodon yonahlossee.*

PAGE 8, genus *Plethodon:* Highton (1979) described *Plethodon websteri* with the common name "Webster's Salamander." This new species should be listed appropriately.

PAGE 10, line 8: Duellman (1977) created a new combination by placing *Acris gryllus paludicola* as a subspecies of *Acris crepitans.* The common name remains the same.

PAGE 11, line 38: Heyer (1978) placed *Leptodactylus labialis* in the synonymy of *Leptodactylus fragilis.* The common name remains the same.

PAGE 12, genus *Rana*: Platz and Mecham (1979) described *Rana chiricahuensis* with the common name "Chiricahua Leopard Frog." This new species should be listed appropriately.

PAGE 16, line 12: Iverson (1979) changed *Kinosternon flavescens stejnegeri* to *K. f. arizonese.* The common name remains the same.

PAGE 19, line 15: Cox and Tanner (1977) considered the genus *Cophosaurus* as a synonym of *Holbrookia.* The common names remain the same.

PAGE 19, line 27: Sanborn and Loomis (1979) elevated *Crotaphytus insularis bicinctores* to specific status as *Crotaphytus bicinctores.* The common name remains the same.

PAGE 33-34, genus *Sonora:* Frost and Van Devender (1979) proposed that *Sonora episcopa* be placed in the synonymy of *Sonora semiannulata,* and that no subspecies be recognized. The common name of *Sonora semiannulata* becomes "Ground Snake."

HERPETOLOGY AT THE DALLAS ZOO

The exhibition of reptiles and amphibians at the Dallas Zoo was initiated rather primitively with the incarceration of a few boa constrictors, a large reticulated python, and a couple of common iguanas. It was a testament to the apparent hardiness of some captive reptiles that these creatures survived for any time at all. Since it was obvious to the Zoo staff that even this paltry assemblage provoked keen public interest, plans were undertaken to develop a comprehensive collection of reptiles and amphibians which would be housed in a modern facility. In honor of the late Director of the Dallas Zoo, the Pierre A. Fontaine Bird and Reptile Building was opened on 4 July 1966. Admittedly the initial task of developing a staff, planning exhibits, and acquiring the animals was arduous, but the Department of Herpetology gradually became an integral part of the Zoo scene.

A large desert ecological exhibit with North American reptiles, especially lizards, has recently been constructed in the front of the building. This enclosure includes live plants and a hibernaculum.

The building houses reptiles, amphibians and tropical birds in naturalistic surroundings. One of the most impressive exhibits is the walk-in rain forest with free-flying birds. Approximately one-hundred exhibits of herpetofauna are available to the visitor and all are presented in elaborate settings which try to duplicate the microhabitats of the taxa within. Extensive use of live and plastic plants, ornamental rock dioramas and graphics hopefully contribute to the overall impression that reptiles and amphibians are beautiful creatures, equipped to survive in a hostile environment. The size of the collection remains rather constant with approximately 300 taxa and 780 individuals. Many are maintained "behind the scenes," due to inability to adapt to the stress of exhibition and for breeding purposes; in addition, since reproduction has been successful, large numbers of young are being raised. Annual mortality has averaged 12% since inception of the Department. Approximately 85 taxa of viperids, 15 varanids and over 60 lizard taxa from other families, 25 boids, 25 colubrids, and 35 chelonians accent

Fig. 3. View of the work area. Exhibit units are on the left.

the collection. Breeding groups are maintained whenever possible and for the first time in the history of the Department, during 1978, reproduction has surpassed attrition through death.

Nearly forty taxa reproduced during a 15 month period. Notable captive births or hatchings for the last few years include the following: *Lampropeltis zonata, L. triangulum arcifera, L. t. amaura, L. t. sinaloae, L. t. ssp., Elaphe bairdi, E. subocularis, E. obsoleta lindheimeri, Liasis childreni, Liasis boa, Epicrates fordi, E. angulifer, Python timoriensis, Candoia bibroni, Crotalus w. willardi, C. adamanteus, C. atrox (albino), C. t. triseriatus, C. t. aquilus, C. lepidus klauberi, C. m. mitchellii, C. m. stephensi, C. pusillus, C. molossus nigrescens, Bothrops godmani, B. nigroviridis aurifer, B. neuwiedi, B. nummifer occidduus, B. n. nigroviridis, Trimeresurus popeorum, Varanus gilleni, V. prasinus, Sauromalus obesus, Sceloporus cyanogenys, S. jarrovi, S. orcutti, Callisaurus draconoides, Dipsosaurus dorsalis, Cnemidophorus tigris, Platysaurus intermedius, Hemitheconyx caudicinctus, Phelsuma abbotti, Phelsuma lineata, Phelsuma madagascariensis, Pachydactylus bibroni, Geoemyda trijuga thermalis, Dendrobates auratus* and *Gekko gecko.*

Geochelone radiata and *Crotalus durissus tzabcan*, placed on breeding loan at the Gladys Porter and Ft. Worth Zoos respectively, have also reproduced. Other breeding loan arrangements have been in effect with the Brookfield, Cincinnati, Houston, Jacksonville, Los Angeles, Lufkin, Memphis, Bronx, Philadelphia, Oklahoma City, San Antonio and Tulsa Zoos.

A large hibernation room has been constructed in order to elicit reproduction from Temperate Zone taxa.

Research, especially regarding behavior, reproduction, and husbandry has accelerated in recent years. Attempts are made, in conjunction with Charles C. Carpenter of the University of Oklahoma, to document behaviors on videotape and film. Joint research projects are currently in effect with colleagues at the University of Texas at Arlington, Southwestern Medical School (a branch of the University of Texas), University of Kansas, University of Florida, Brooklyn College, and various zoological gardens. To date, nearly fifty contributions have been published by members of the Department. Through the generosity of colleagues, many living specimens have been deposited with the understanding that the animals be preserved upon death. Specimens have been placed by Tom Van Devender (University of Arizona), Wayne Van Devender and Arnold Kluge (University of Michigan), John Wright (Los Angeles County Museum) and Wayne Seifert (Dallas Museum of Natural History). Jonathan A. Campbell and Barry L. Armstrong have deposited an extensive collection of rare Mexican and Central American reptiles and amphibians, including nearly 40 taxa of pit vipers. To these generous colleagues, heartfelt thanks are extended.

Specimens upon death are rarely discarded. Those which are accompanied by locality data or are vouchers are placed in a systematic museum collection. Others without data, including those necropsied, are provided to institutions for study purposes. The staff is especially pleased to offer the facilities to researchers who are doing ethological or other research. Examples of research which has been accomplished include constricting behavior in boids and colubrids, reaction of pit vipers to kingsnake skin secretions, agamid feeding behavior, analysis of shed skins with the use of scanning electron microscopy, turtle righting reflexes, ophiophagous snake feeding behavior, collection of microorganisms and endoparasites, feeding behavior in rattlesnakes, gekkonid behavior, karyology and the inclusion of specimens in various taxonomic studies. Biologists in the region have regularly offered a tour of the facility as an adjunct to class work for students.

Many photographers have used the facility and nearly all rare herpetofauna have been photographed for a permanent record.

It is the intention of the staff of the Department of Herpetology to develop a continual multifaceted approach to zoo herpetology, namely, to maintain reptiles and amphibians successfully in attractive exhibits, provide an educational experience for the zoo visitor, encourage reproduction, document behavioral patterns, improve husbandry techniques, stimulate inter-institutional programs and most importantly, become a reservoir for endangered species.

A WINTER SURFACE OBSERVATION OF A REDBACK SALAMANDER, *PLETHODON CINEREUS*, IN NORTHERN OHIO

Several authors have reported of the hibernacula of *Plethodon cinereus* (Hoff, 1977; Taub, 1961; Vernberg, 1953). Most reports indicate that hibernacula are located beneath the soil surface in a variety of habitats (below tree stumps, in ant mounds, near woodchuck burrows). However, Cooper (1956) reports an aquatic hibernaculum.

On 17 December 1977, a search of a known locality for *P. c. cinereus* in Lucas County, Ohio revealed a single specimen of the lead-backed color phase (total body length 6.5 cm) under a fallen log on a southward-facing slope at 0750h. The individual made no attempt to escape, although it did move in a slow, coordinated manner when touched. Air temperature, recorded immediately with a previously-calibrated mercury thermometer, was 1°C. Soil in this locality is sandy with leaf litter. Oaks (*Quercus* sp.) are the predominant vegetation. Snow cover was present at depths varying from 1.5-3.0 cm.

Taub (1961) stated that *P. cinereus* in New Jersey were never found at the ground surface at air temperatures below 4° C. Vernberg (1953) found that the lowest surface temperature tolerated by Indiana specimens of *P. cinereus* in an outdoor artificial hibernaculum was 4° C. Soil temperature near salamanders which had burrowed into the substrate was 3°C. Hoff (1977) found 86 hibernating *P. cinereus* in Massachusetts beneath stumps of recently-cut white oaks. Soil temperature was 5-9°C and activity was observed in all individuals.

The present observation represents a marginally different surface temperature at which *P. cinereus* has been recorded as capable of coordinated movement.

We wish to thank Dr. Robert E. Gatten, Jr. for his assistance in the preparation of this manuscript.

PURE WHITE RATTLESNAKE

An aberrant female specimen of Eastern Diamondback Rattlesnake, *Crotalus adamanteus* was collected as a 20" juvenile, displaying only the first button, crossing a road approx. 3 miles N. W. of Palm City, Martin County, Florida, on September 19, 1975. She was given to the authors and raised by them since. Nearing 4 years of age, she measures 55" and is still in perfect health.

"Snowflake" apparently lacks all pigment, though the iridophores probably account for the bluish-grey color surrounding the iris and the prismatic luster of her scales after a shed. As a juvenile, she had a pinkish cast due to the somewhat transparent scales and skin, but now she looks pearl white since the scales have enlarged and thickened. No trace of pattern is visible. Blood vessels can clearly be seen below the skin when a meal distends her.

Two other specimens exhibiting this type of aberrancy have been seen by the authors; a Texas Rat Snake, *Elaphe o. lindheimeri*, at the Houston Zoo, Texas, and a Cobra, *Naja naja*, at the Black Hills Reptile Gardens, South Dakota. Plans are to breed "Snowflake" in an attempt to learn how this aberration is inherited.

NOTES ON THE SEXUAL BEHAVIOR AND THE REPRODUCTION OF *TEIUS TEYOU* (LACERTILIA: TEIIDAE)

Teius teyou is a common Uruguayan species found not only in rocky areas but in sandy zones as well. As the sexual behavior of teiids is poorly known, and as little information is available on the reproduction of this species, the following notes may be of interest.

These observations were made on December 12, 1977, in a sandy area with shrubby vegetation (*Acacia longifolia*) at Canelones Department, Uruguay. A big male was observed walking slowly among the shrubs. Tongue flicks were occasionally directed at the ground. Minutes later, the male started to follow a nearby female. She attempted to move away, but the male pursued, biting her on the dorsum, sides and extremities. The female would free herself, and again retreat. I observed a repeated succession of retreats by the female, accompanied by pursuit and biting by the male. The couple moved several meters during this activity.

The male on one occasion mounted the female and bit her behind the neck. The female remained motionless, and the male bit her dorso-lateral zone, ahead of one of her hind legs. The male moved his trunk and kept his body close to the female's. His cloacal region was in a vertical position. The female moved her body so her cloaca was near the male's, and copulation commenced. The male everted both hemipenes, although only one was utilized. As copulation concluded, the female moved away.

The male then started some post-copulatory activities. He stretched his hind legs, so his cloaca was elevated above the ground. He then retracted his hemipenes, and dragged his cloacal zone on the ground; he also rubbed his lips against the ground and the nearby vegetation. He remained motionless for some minutes, basking, and then walked slowly between the shrubs to about 100 m from the place where copulation took place.

Carpenter (1962) and Müller (1971) described the sexual behavior of *Cnemidophorus sexlineatus* and *C. lemniscatus* respectively. Their observations are similar to these on *T. teyou*. The male I observed did not do any pre-copulatory rubbing. The walking and the exploration of the ground displayed by this male just before copulation has been observed in this species only in this case. This suggests that this behavioral unit is related to sexual behavior. The mount also present in *C. sexlineatus* and *C. lemniscatus* (Carpenter, 1962; Müller, 1971) could be the unit necessary to go from the reiterated pre-copulatory phase to the copulatory one.

Copulations were observed from late October to early December. In November, eggs have been found in *Acromyrmex* ant hills (Vaz-Ferreira, *et al.*, 1970). I have observed a clutch of 8 eggs under a rock (49 x 26 cm, and 15 cm high) at Valle Edén, Tacuarembó Department. The eggs were buried, and only one was visible. A complicated channel system was found under the rocks around the nest. In seven measured eggs, the long axis ranged from 20.0 to 16.9 mm ($\bar{x}$ = 10.3 mm), and the short axis from 12.0 to 14.1 mm ($\bar{x}$ = 13.2 mm). These values are different from those reported by Vaz-Ferreira, *et al.* (1970), who found that 21.4 mm was the minimum long axis and 13.3 mm was the minimum short axis observed. Eight is also a new maximum record of eggs in a clutch.

T. teyou is unique among the lizards of Uruguay as it optionally lays eggs in ant hills or under rocks. It is also apparently a K-strategist species: it is a large, long lived lizard, and a presumed single-brooded species. The eggs laid in ant hills are in a favorable environment, with fairly constant temperature, high humidity and the absence of harmful fungus. The eggs under rocks are affected by the great variations of temperature and rain of the Uruguayan summer. There is no data on nest predators.

It could be assumed that those genotypes that lay their eggs in ant hills could be favored over those that lay their eggs under rocks. This duality in nest site appears to be an interesting topic for future research.

I thank F. G. Costa, A. Gascón and A. Langguth for their comments on the manuscript. Thanks are also expressed to Ramona Robertson for retyping the draft. This note was prepared at the Departamento de Zoología-Vertebrados, Facultad de Humanidades y Ciencias (Uruguay).

HERPETOLOGICAL HUSBANDRY

SUGGESTIONS FOR THE *POST-MORTEM* EXAMINATION OF REPTILES

Collections of living reptiles are unique and valuable biological resources. The purpose of this paper is to encourage herpetologists to enhance the value of this resource by obtaining useful data following the death of any specimen.

Why perform necropsies or "What can be learned from a dead snake?"

Death is the inevitable outcome of life. Too often, we use this truth as an excuse for failing to derive any information from specimens in reptile collections "after the fact." A careful *post-mortem* examination (necropsy) can provide the interested curator and herpetologist, as well as the scientific community at large, with valuable data, much of which is immediately applicable to the living collection. Among other things, a necropsy may provide data on:

1) The cause of death;

2) The existence of infectious diseases which may threaten other specimens;

3) The existence of intercurrent or clinically silent diseases which may not be fatal, but which sap vitality, reduce the fecundity and otherwise, affect the health, value and appearance of specimens;

4) Correlation of clinical signs and tissue changes—Adequate clinical care of ill animals simply cannot be provided if no one knows, for example, what the possible causes of abdominal distension in snakes are; how rapidly each may progress; which occur most frequently; what the effects of the treatment were, etc.;

5) Efficacy of treatment—If we treat an animal for some clinical condition and it dies, the treatment was obviously no good and should not be used again - or should it? Did the specimen die of the condition for which it was being treated? Was the clinical diagnosis both correct and complete? Necropsy may provide at least partial answers to these and similar questions;

6) Incidence of various types of diseases in captive reptile collections—This endeavor is no less important than the short-term studies, but requires the help and cooperation of many collections to compile adequate statistics. One current effort in this area is the Registry of Tumors in Lower Animals at the Smithsonian Institution. Help yourself and help your colleagues by contributing to these collections.

One final plea for the necrospy: it provides us all an opportunity to refresh and add to our knowledge of normal anatomy and even to determine what "normal" anatomy is in some of the more exotic specimens. All too often, normal tissues are submitted to laboratories identified as "worms," "tumors," etc. It is appalling to think how many lesions may be dismissed as "normal"!

What are the objectives? or "I cut up the carcass just like you said and I didn't learn anything!"

The necropsy can provide reams of valuable and useful information, but not without a little foresight. Before anything at all is done with the animal, the investigator must decide what goals are to be achieved by the necropsy and how these goals rank in importance. The goals cannot be achieved without adequate advance preparation. The following table provides some examples.

PROBLEM OR QUESTION	GOAL	BE PREPARED TO
Infectious disease suspected	Identify causative agent.	Collect samples aseptically; provide samples to lab and/or identify agent(s); provide appropriate storage if necessary.
Chemical agent suspected	Identify causative chemical.	Collect proper fluids or tissue in appropriate containers; provide means to identify suspected chemical; store sample properly.
Confirm clinical interpretation	Account for each major clinical sign; assess effects of treatment; render diagnosis.	Examine each organ systematically; collect appropriate specimens for more detailed study (*e.g.* - fixed tissue for histopathology).

If a suspected disease is under study by a central registry, provide specimens and other documentation adequate for the purposes of the registry collection. Give detailed descriptions of autopsy findings. Document with photographs. Collect specialized materials, (*e.g.* fix tissues for electron microscopy; collect living cells for tissue culture).

If the dead animal is unusual enough to warrant further taxonomic study, preserve the specimen so that accurate taxonomic data can be obtained. Identify and preserve key organs or tissues required for accurate taxonomic classification. Accurately record findings which cannot be preserved.

Some Suggested Techniques or "There's More Than One Way To Shell a Turtle."

A necropsy is a systematic examination of body organs and tissues following death. A little attention to technique will make the whole thing go smoother and easier. Some suggestions for performing a necropsy follow. Obviously, the goals of the necropsy may dictate some changes in the approach. These suggestions provide a starting point.

Some cardinal necropsy rules are:

1. DON'T WAIT - Spoiled tissues are no help to anyone.
2. BE PREPARED - Sterile equipment, culture media, preservatives, arrangements with consultants, etc. all require forethought. Do it now.
3. FREEZING RUINS TISSUES for microscopic study. Hold dead animals at refrigerator temperatures. Do the necropsy promptly. A frozen carcass *may* be acceptable for preservation of infectious or chemical agents of disease. Check with your lab or an appropriate reference to confirm this for the agents you suspect.
4. PICK and RANK the GOALS.
5. HAVE A PLAN - Why are you doing the necropsy? Which goal is the primary one and which are secondary ones? You can usually achieve more than one objective -especially with a little foresight.
6. Take notes and write it all down.
7. Save samples of ALL major organs and tissues.
8. Use sharp instruments.
9. Cut thin (2-4 mm) pieces of tissue with a SHARP BLADE (not scissors) for fixation.
10. Use 10 to 20 times as much formalin as you have tissue. Use neutral buffered formalin if at all possible.
11. Label and date ALL containers.
12. Store properly.

The Basic Necropsy Procedure may be performed as follows:

1) Examine the entire body, this includes all body openings, body coverings, eyes, oral cavity (be careful with the fangs of venomous snakes), cloaca, penis, etc. Look into and under scales, skin folds, shell crevices, eyelids, etc. Look for blood, discharges, foreign bodies, parasites, food, wounds, etc. The shell of turtles should be specifically examined for cracks, separations and other evidence of injury.

2) Lay the body on its back and make a midline incision through the skin from the end of the lower jaw all the way to the posterior end of the body cavity. If a specimen is to be saved for museum study, cut at juncture of ventrals with dorsals. Carefully remove the skin from the ventral and lateral body walls. Carefully describe any lesions associated with the skin or shell and remove those lesions along with the skin. Observe the condition of the muscle and subcutaneous tissue. Now cut through the ventral body wall itself and expose the body cavity. The plastron and carapace of turtles should be separated at the bridge with a butcher saw, coarse bladed hacksaw or bone cutters. The plastron is then removed by cutting the underlying muscle to reveal the pleuro-peritoneal space. Cut the sternum at the costochondral junctions and sever the pectoral and pelvic girdles.

3) The usual time for collecting samples for microbiology, chemistry, hematology, etc. is now. Collect the specimens for microbiology carefully. Choose both obviously abnormal and normal areas of the organ(s) being sampled and collect the "cleanest" organ system first (e.g.-collect a specimen of lung before collecting intestine).

4) During the entire necropsy, look for changes in: anatomic position, sizes of organs and tissues, shape, color and consistency of organs and tissues. Look for the presence of exudates, excessive fluid, hemorrhage, discharges, foreign materials, parasites, etc.

5) Identify and remove the thyroid, parathyroid and thymus glands. Some review of normal anatomy will be helpful since there are often marked differences in location among various species of reptiles.

6) Start with the larynx and remove the cardiopulmonary system in one unit by dissecting away the soft tissue of the pharynx, tongue and esophagus. Examine the tissues. Open the lungs by opening the major bronchi with scissors. Open and examine the heart chambers and great vessels.

7) Identify the liver and gall bladder. Before removing, open the segment of intestine into which the bile duct drains and put slight pressure on the gall bladder. Free flow of bile indicates an open bile duct. Remove liver and gall bladder. Make multiple slices through the liver and look at the cut surfaces.

8) Remove and examine the spleen. Make multiple incisions through the organ and examine the cut surfaces. (If the spleen and pancreas are intimately attached defer and remove both together in step 10.)

9) Identify, remove and examine the genital system.

10) Remove the digestive system by dissecting the tongue free of its muscular and fascial attachments and remove tongue, esophagus, stomach and intestine to the cloaca. Observe the pancreas and dissect it free of the intestine after probing the pancreatic duct. Open the gastrointestinal tract and observe the contents and the mucosal surfaces at all levels.

11) Identify and remove the adrenals.

12) Remove the kidneys, ureters and cloaca. Probe the ureters for patency and make multiple incisions through the kidneys.

13) Examine the body cavity and remove segments of muscle covered with mesothelium (the lining of the cavity).

14) Open and explore the nasal cavity and sinuses.

15) Lay the body on the ventral surface and

remove the rest of the skin. Save a portion of skin (save it all if rare).

16) Remove both eyes and orbital contents. Dissect the globes free of muscle, fat, glands, etc. but do not open them.

17) Cut through the dorsal vertebral arches and the skull. Remove the brain, pituitary and spinal column. Do not slice these tissues until they have fixed 24-48 hours.

18) Open and examine the marrow cavity of at least one long bone. Save at least one bone with marrow and a joint surface still attached.

19) Incise the skeletal muscles and open at least some major joints. Examine the vertebral column and the appendicular skeleton.

CONCLUSION

Necropsy of specimens is a highly rewarding activity with many immediate and long term benefits. Foresight, a plan and some practice will result in a high yield of valuable data and deep personal satisfaction.

CAPTIVE REPRODUCTION IN THE SCARLET KINGSNAKE, *LAMPROPELTIS TRIANGULUM ELAPSOIDES* (HOLBROOK)

Data on the eggs and young of the scarlet kingsnake, *Lampropeltis triangulum elapsoides* (Holbrook), have been provided by Allen (1932), Duellman and Schwartz (1957), Wright and Wright (1957), Palmer (1961), Groves and Sachs (1973), Mount (1975), and Groves and Assetto (1976). This information, however, is restricted to either eggs found in nature or eggs and young from wild-caught gravid females. Dates of copulation,egg-laying, and hatching in captivity were presented by Williams (1978), but no measurements were provided for eggs and young.

A female *L. t. elapsoides* (572 mm total length) collected 25 March 1971, 2.2 km SW Tillman, Jasper Co., South Carolina and a male (483 mm total length) were housed in separate 38 liter (10 gal.) aquaria with paper towel substrates and pine bark for hiding. Fresh water was provided daily and each snake was fed two ground skinks, *Leiolopisma laterale*, or green anoles, *Anolis carolinensis*, weekly. Ambient cage temperature varied between 21-28° C. Windows with a southern exposure provided a natural photoperiod. The male was placed with the female on 15 April 1971.

Copulation was already in progress when observed on 27 April 1971 at 0115. Intromission and coitus were similar to that observed by Gillingham, *et al.* (1977) and Murphy, *et al.* (1978). The male was observed pressing the female down middorsally with four body loops. The female's venter rested upon the substratum with her tail slightly raised. The male's tail was in a ventrolateral position and under the female's tail without encircling it. The male rubbed his chin lightly along the female's neck for 3.5 minutes; tongue flicks occurred at 4-6 second intervals for 2 minutes. After *ca.* 30 minutes, the male relaxed, moved slightly forward, and retracted his hemipenis. The snakes slowly crawled away from each other with their tails raised to a 40-45° angle from the no substratum. The tails were lowered slowly, after 2 minutes, as they crawled about the cage.

The female's appetite thereafter decreased and her girth increased rapidly; bulges appeared along the posterior one-third of her body by 14 May 1971. The pair was separated on 19 May 1971.

On 6 June 1971 at 1125, four eggs were found under a piece of pine bark in the cage. The eggs were soft and adherent. Length and diameter were measured with a vernier caliper; weights were taken. The range in variation was: length, 19.0-31.7 mm (mean 23.7) and diameter, 9.3-12.1 mm (mean 10.4).

The eggs were incubated between layers of dampened paper towels in a .943 liter (1 qt.) plastic freezer container sealed with clear plastic wrap and maintained at 25-31° C. The eggs were checked at weekly intervals for desiccation and fungal infection.

At 1540 on 11 August 1971 the heads of the neonates protruded from longitudinal dorsal slits in two eggs. The remaining two eggs began to hatch at 1610 the same day. All four snakes had completely freed themselves from the shells by 0825 on 12 August 1971. The hatchlings behaved defensively and struck at objects moved near them. Juvenile coloration differed from the adults; the light body rings were white instead of yellow. The lengths were measured by gently stretching each hatchling along a metric rule. The range in length was: 139.7-177.8 mm total length (mean 152.4). No weights were recorded.

After ecdysis on 20 August 1971, the hatchlings were offered the amputated tails of ground skinks, which were eagerly accepted. Each juvenile ate two adult ground skinks weekly until the snakes were released 24 October 1971.

ACKNOWLEDGEMENTS

I thank Bern W. Tryon for his assistance in the field and for his encouragement. I wish to thank R. Howard Hunt for critically reviewing this paper.

NEW BOOKS

The Royal Zoological Society of South Australia announces the publication of THE STATUS OF ENDANGERED AUSTRALASIAN WILDLIFE, a 220 page book containing seventeen chapters on the wildlife of Australia, New Zealand and New Guinea. Endorsed by the IUCN, this book attempts to establish which animals are genuinely endangered in the area covered. Available from: The Curator, Royal Zoological Society of South Australia, Frome Road, Adelaide, South Australia 5000, Australia. Price: $8.15 postpaid (Australian currency).

Smithsonian Institution Press has recently published two books that are of considerable interest to herpetologists. The COMPOSITION OF SCIENTIFIC WORDS (882 pages, 6 x 9", cloth, $12.50) is a reprint of Roland W. Brown's 1956 classic dictionary. The first part of the book offers a brief discussion on the elementary structure of English, Greek, and Latin with a guide to the formulation of technical terms and scientific names. The majority of the volume is an alphabetical list of key words giving their synonyms and cognates in English, Greek, and Latin with occasional additions from thirty-eight other languages or dialects. THE ENGLISH-RUSSIAN: RUSSIAN-ENGLISH DICTIONARY OF VERTEBRATE ZOOLOGY by George J. Jacobs (48 pages, 9 x 10" paper, $4.25) provides a list of terms of special interest to vertebrate systematists and anatomists with a strong emphasis on amphibians and reptiles. Of particular interest will be the "root" words for anatomical terms and the matching Russian common names for herps with their Latin taxonomic equivalents and vice versa. Both books are available for purchase from the Smithsonian Institution Press, P.O. Box 1579, Washington, D. C. 20013.

Society for the Study of Amphibians and Reptiles

Handbook of Snakes

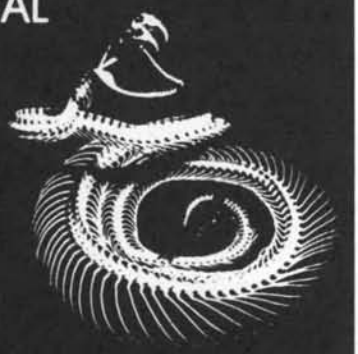
VOLUME 3: BIBLIOGRAPHY

about 200 pages, with new introduction, portrait; 6 x 9 inches

ALBERT HAZEN WRIGHT and Anna Allen Wright's *Handbook of Snakes of the United States and Canada* was first issued by Cornell University Press in 1957. The accompanying bibliography, which gives full citations for the literature references abbreviated in volumes 1 and 2, was not issued until 1962 and published privately by the Wrights themselves. The continuing demand for the *Handbook* caused Cornell to reissue it several times since but the bibliography, which is essential to the full use of those volumes, has been unavailable for nearly a decade and yet it is absolutely necessary for any comprehensive library on North American reptiles.

The bibliography is a detailed list of 3500 references arranged in several sections. There is a general list given chronologically and divided into named periods; a list of literature according to life zones and ecological classifications; and finally a geographic listing by state and province. The extensive bibliography on pitvipers in Klauber's *Rattlesnakes* overlaps only slightly with the Wrights' list so that together these two works provide the most complete bibliography of the snakes of North America.

Prices and Ordering



SSAR members, if ordered *before February 15* . . . . . $10 clothbound

Institutions; Non-members; All orders received after February 15 . . . . $15 clothbound

Orders should be placed now since the book, which was published in December 1979, was issued in an edition limited to a few hundred copies. To take advantage of the special publication rates SSAR members must send their orders *before February 15.* Address orders to: Dr. D. H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Make checks payable to "SSAR"; receipt on request only. *Prices include packing and shipping.*

A price-list of other Society publications can be obtained on request from Dr. Taylor.

HERPETOLOGICAL SKELETONS SKULLS

Prepared for educational and display needs.

Over 1000 specimens in stock. From 2 in. tree frog to 7 ft. monitor lizard and 16 ft. python.

We welcome your requests and inquiries.

The Reptile Ear

Its Structure and Function

ERNEST GLEN WEVER

". . . Well-organized, well-illustrated, and clearly written . . . Although several recent reviews of the reptilian ear have appeared, none is as comprehensive as this one. It is a reference book that should become an essential addition to all scientific and biological libraries."
—O.W. Henson, Jr., *American Scientist*

"In this work Wever . . . presents an extensive study of the structure and function of the reptilian peripheral auditory system . . . This book will be appreciated by biologists who are interested in the comparative structure and function of the ears of the different groups of reptiles as an aid to determining the taxonomic and phylogenetic relations between those subgroups of reptiles about which controversy still exists . . . As Wever readably demonstrates, the evolution of the reptilian ear has supplied us with many variations on the basic vertebrate ear which should stimulate our thoughts and be useful as experimental models for investigating the basic peripheral mechanisms of hearing." —Michael J. Mulroy, *Science*

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The *standard format* for a geographic distribution record is:

Scientific name (common name) as it appears in *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (Collins, Huheey, Knight and Smith, 1978). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalog number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, Univ. of Kansas, Lawrence, KS 66045. Short manuscripts are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in *Herpetological Review* is: Jones, J. 1977. Geographic distribution: *Rana pipiens*. SSAR Herp. Review 8(1): 1.

ANURA

BUFO DEBILIS INSIDIOR (Western Green Toad). USA: KANSAS: Wallace Co: 6.4 km S Wallace, Sec. 7, T14S, R38W. 10 June 1979. S. Roth. Verified by H. S. Fitch, Univ. Kansas, Lawrence (KU 182086). First record for the county, fourth known locality in Kansas, and the first specimen taken in Kansas since 1928 (Taylor, 1929. Univ. Kansas Sci. Bull., 19:63-65). The female specimen was collected while active by day on the south-facing slope of a dry east-west ravine below a bluff on rocky, sandy soil. Plant associates were *Yucca* and *Gaillardia*. Herpetofaunal associates were *Holbrookia maculata* and *Cnemidophorus sexlineatus*.

Submitted by STANLEY D. ROTH, Biology Department, Lawrence High School, Lawrence, Kansas 66044, and JOSEPH T. COLLINS, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

HYLA ARENICOLOR (Canyon Treefrog). USA: NEW MEXICO: Luna Co: Big Florida Mountains, T 25S, R7W, S31, 0.9 km W and 0.1 km S Byers Spring. 11 July 1978. S.C. Belfit. Verified by A. Price. New Mexico State University Collection (NMSU 5495). This recently metamorphosed adult was collected from a spring box at 1682m. Mountain riparian habitat extends into a steep sided box canyon below the spring. There are several other permanent water sources in the Big Florida Mountains in which this species is likely to occur. Another specimen was collected at Cook's Peak, east side, 27 Sept. 1970. D.L. Hunt. Verified by A. Price. New Mexico State University Collection (NMSU 3823). These records represent the only localities available for the species in Luna County. A distribution survey for seven southwestern New Mexico counties which utilized most of the major herpetological collections in the United States (available from the Las Cruces District office of the Bureau of Land Management, Las Cruces, N.M.) lists no other records of *Hyla arenicolor* from Luna County.

Submitted by SCOTT C. BELFIT, Sci. Dept., Webb School, Bell Buckle, Tennessee, 37020. ●

TESTUDINES

STERNOTHERUS ODORATUS (Stinkpot). USA: NEW YORK: Jefferson Co: SE shore of Ironsides Island, Township of Alexandria. 28 May 1979. P.J. Petokas and M. Rooks. Collection of P.J. Petokas (PJP 120 shell only). NEW YORK: St. Lawrence County: Sheepshead Bay, Township of Hammond. 5 September 1977. P.J. Petokas and S. Archer. One individual captured, marked and released. NEW YORK: Jefferson Co: Point Marguarite Marsh, Township of Alexandria. 20 August 1977. P.J. Petokas, D. Phillips and T. Black. Three individuals captured, marked and released. NEW YORK: Jefferson County: Cranberry Creek-Goose Bay Marsh, Township of Alexandria. 30 June 1977. P.J. Petokas, D. Phillips and T. Black. One individual captured, marked and released. Specimens verified by M. M. Alexander. This report provides the first documented record of this species in northern New York. Logier and Toner (1961, Check List of the Amphibians and Reptiles of Canada and Alaska, Royal Ontario Mus. Contr. No. 53) show range east to the St. Lawrence River in the Province of Ontario, Canada.

Submitted by PETER J. PETOKAS, U.S. Fish and Wildlife Service, 100 Grange Place, Cortland, New York 13045 and MAURICE M. ALEXANDER, Department of Environmental and Forest Biology, SUNY College of Environmental Science and Forestry, Syracuse, New York 13210. ●

SAURIA

ANNIELLA PULCHRA (California Legless Lizard). USA: CALIFORNIA: San Bernardino Co: Big Morongo Wildlife Reserve, Morongo Valley. 14 April 1975. D. Wilson. Identified by J. W. Cornett. Specimen given to Ranger Wilson for release. Most northeastern record of this species. Extends previous known range 11 km northeast (Stebbins, R. 1966. *A Field Guide to Western Reptiles and Amphibians*, Houghton Mifflin Co., Boston). At least two additional observations have been made since the above discovery.

Submitted by JAMES W. CORNETT, Natural Science Department, Palm Springs Desert Museum, Palm Springs, California 92263. ●

GERRHONOTUS LIOCEPHALIS INFERNALIS (Texas alligator lizard). USA: TEXAS: Fayette Co: Monument Hill and Kreische Brewery State Historic Sites, 3 km south LaGrange. 1 September 1978. I.L. Jones and K. Von Minder. Identified by R. W. Neck and D. H. Riskind. Texas Memorial Museum Z1978-2345. Frisch Auf Golf Course, 3 km SW LaGrange. 6 November 1978. L. Evans. Identified by K. Peterson. Karl Peterson private collection (to be deposited at Univ. Texas at Arlington). Heretofore considered to be endemic to the Texas Hill Country and adjacent physiographically similar areas in western Texas and northern Mexico (Raun & Gehlbach, 1972. Dallas Mus. Nat. Hist., Bull. 2:I-61), a viable population has been located 100 km SE of previous nearest specimens from Austin, Travis County. Habitat is wooded, dissected massif of calcareous Oakville Escarpment which supports flora and fauna characterized by outlying populations of species with Hill Country affinities.

Submitted by RAYMOND W. NECK and DAVID H. RISKIND, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744; KARL PETERSON, Department of Herpetology, Houston Zoological Gardens, Houston, Texas 77001. ●

SCELOPORUS UNDULATUS HYACINTHINUS (Northern Fence Lizard). USA: MISSOURI: Pike Co: 3.9 km W Jct. Mo. Rts. 79 & TT on TT (91°13'45"W; 39°33'39"N), 152m. Taken on limestone rocks next to road. 8 April 1978. N. Haskell Jr. Verified by R. W. Axtell, S. Illinois Univ., Edwardsville, (SIUE 2623). Extends range 48.9 km ENE of previous record, Mark Twain State Park, Monroe County (Anderson, 1965, The Reptiles of Missouri, Univ. Mo. Press, Columbia, 330 pp.).

Submitted by NORMAL HASKELL, Jr., 1110 Douglas, Alton, Illinois 62002. ●

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: MISSOURI: Crawford Co: 15.7 km SW Cuba. 16 August 1977. W.J. Drda and D.A. Kluepfel. Private collection of W.J. Drda. First record for Crawford County and first specimens from the Meramec River. Extends range 77.4 km ESE of the record in Miller County (Iberia) and 60.9 km NNE of the record in Dent County (Ashley Creek) (Anderson, 1965, *Reptiles of Missouri*, Univ. Missouri Press, Columbia, 330 pp.).

Submitted by WAYNE J. DRDA, Fox Senior High School, Arnold, Missouri 63010 and DANIEL A. KLUEPFEL, University of Missouri at St. Louis, St. Louis, Missouri 63121. ●

CEMOPHORA COCCINEA COPEI (Northern scarlet snake). USA: OKLAHOMA: Cleveland Co: 14 km SE Norman. 3 August 1978. R.L. Ball, Oklahoma Baptist Univ. Webster Nat. Hist. Mus. (WNHM 238). Extends Oklahoma range 88 km W and 81 km S of the two nearest previous records from Meridian, Logan County, and near the Seminole-Hughes County line (Webb, 1970, Reptiles of Oklahoma, Univ. of Oklahoma Press, 370 pp.).

Submitted by ROBERT L. BALL, 616 W. Walnut St., Tecumseh, Oklahoma 74873. ●

CROTALUS RUBER (Red Diamond Rattlesnake). USA: CALIFORNIA: Riverside Co: Desert Hot Springs. 20 March 1976. J. W. Cornett and J. Bredesky. Identified by J. W. Cornett. Specimen released. Most northeastern record of this species. Extends previous known range 6 km east into creosote scrub community (Klauber. 1972. *Rattlesnakes*, Univ. California Press, Berkeley, 1533 pp.).

Submitted by JAMES W. CORNETT, Natural Science Department, Palm Springs Desert Museum, Palm Springs, California 92263. ●

RAMPHOTYPHLOPS BRAMINUS (Asian Blind Snake). MEXICO: Baja California del Sur: San Ignacio. 8 August 1963. J. R. Heinricks. Identified by R. W. Murphy. Brigham Young University (BYU 2244l). First record of the family Typhlopidae in Baja California. Collected at 1200 hrs within city limits as it crossed a dirt road. Previously recorded from the states of Guerrero, Michoacan and Sinaloa, Mexico (Smith, H. M. and R. B. Smith, 1976, Synopsis of the Herpetofauna of Mexico, Vol. 3, John Johnson, N. Bennington, Vermont). This is the second documented record of an introduced herpetofaunal species in Baja California; *Rana catesbeiana* was previously reported (Mullen, D. A., 1976, Herp. Review, 7(3):122). If this species of snake is indeed parthenogenic (McDowell, 1974, J. Herp., 8(1):1-57), it is likely to become established on the peninsula at other sites containing permanent water.

Submitted by ROBERT W. MURPHY, Department of Biology, University of California, 405 Hilgard Ave., Los Angeles, California 90024, and JOHN R. OTTLEY, Department of Herpetology, Monte L. Bean Life Science Museum, 290 MLBM, Brigham Young University, Provo, Utah 84602. ●

THAMNOPHIS CYRTOPSIS OCELLATUS (Eastern Blackneck Garter Snake). USA: TEXAS: Bell Co: *ca.* 20 km NNE Killeen on the Fort Hood Military Reservation; 30 August 1978. B. G. Stewart and G. A. Splawn. Louisiana St. Univ., Mus. Zool. (LSUMZ 36995). First specimen from county and extension of range about 80 km N of Travis County and 100 km ENE of Llano County (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist., Bull. 2:1-61). Also represents the first record from the Brazos River Drainage Basin. The vegetation on Fort Hood is a northeastern extension of that typical of the Edwards Plateau of central Texas where *T. cyrtopsis* is fairly common. Thus, its occurrence on Fort Hood was to be expected. The species was also observed several times on Fort Hood (Coryell and Bell Counties) by F. E. Potter, Jr. in 1953.

Submitted by BRUCE STEWART, Environmental Division of Espey, Huston, and Associates, Inc., 3010 S. Lamar, Austin, Texas, 78704, and FLOYD E. POTTER, Jr., Texas Parks and Wildlife Department, 4200 Smith School Rd., Austin, Texas, 78744. ●

TEXAS AMPHIBIANS AND REPTILES: SOME NEW DISTRIBUTIONAL RECORDS, PART II

INTRODUCTION

This is the second serial report of new distributional records of Texas amphibians and reptiles, substantiated with specimens in the Texas A & I University Collections (TAIC). These new records are additions to those summarized by Karges (1978) since Raun and Gehlbach (1972). Nomenclature follows Collins, *et al.* (1978) except where noted, and verification of identifications is by the author. Parenthetical numbers refer to the number of individuals, in a series, with a single TAIC catalog number.

I am appreciative of Dr. Allan H. Chaney for allowing me access to the Texas A & I Collections, and for his suggestions. I also thank Richard R. Schmidt, for his contributions in the field.

SALIENTIA

BUFO DEBILIS (Green Toad): KLEBERG Co. Thirteen specimens from several localities collected over several years. TAIC-299, 346, 780, 830, 871(6) 957, 1452, 1468.

HYLA CINEREA (Green Treefrog): GOLIAD Co. San Antonio River crossing off of U.S. 183, ca. 3 km S Goliad. 10 February 1969. J.

Reptile HOT BLOCK

Research has shown that "coldblooded" animals absorb heat from the surface they lie on. The HOT BLOCK provides a safe, water-resistant, thin warm surface that can be placed at the bottom of an animal's cage, either on the surface or buried under a suitable substrate.

HIDING PLACES

A unique concept in providing security for a small pet. hollow half logs provide a natural HIDING PLACE in which the animal can seek shelter.

Evergreen

TERRARIUM MOSS

A natural moss, fixed and enhanced in color, so the bright natural color never fades. It is also sealed in a special Latex bath so it may be kept continously damp without loss of color or fear of deteriation.

TERRAFAUNA p.o. box 3425, Van Nuys, Ca. 91407

and S. Davis. TAIC-1757(4). KLEBERG Co. 3.2 km S Kingsville. 17 September 1975. R. Schmidt and J. Karges. TAIC-3860(2).

HYLA CRUCIFER (Spring Peeper): SAN JACINTO Co. Double Lakes, Sam Houston National Forest. 16 March 1968. B. Chapman. TAIC-1570.

HYPOPACHUS VARIOLOSUS (Sheep Frog): WILLACY Co. Thirteen specimens were collected during 1972 at several locations. TAIC-2987, 2909, 3212, 3240(10).

PSEUDACRIS CLARKI (Spotted Chorus Frog): NUECES Co. Three groups of specimens were collected at 5.1 km E Driscoll, Flour Bluff, and Corpus Christi, respectively in order of increasing catalog numbers. All were collected in 1972 by different collectors. TAIC-794(9), 1488(2), 2081(2).

RANA CATESBEIANA (Bullfrog): BROWN Co. Weedon's Quarry on FM 2559, but precise locality of the collection site is unknown. 7 October 1968. R. Zimmerman, *et al.* TAIC-1689. LA SALLE Co. 24 km S Cotulla, off FM 468. 8 & 9 April 1967. A Chaney *et at.* TAIC-648(15). MATAGORDA Co. The total of 48 specimens are from numerous localities within the county, and have been collected by Texas A & I University field crews on several annual field trips. TAIC-2452(8), 2607(13), 2994, 3143(2), 3431, 3494, 3611(8), 3778. SAN SABA Co. 1.6 km SW Bend on FM 580. 4 October 1968. R. Zimmerman, *et al.* TAIC-1684. WALLER Co. 9.6 km NW Katy. Spring, 1967. W. Kretz. TAIC-634(2). WEBB Co. 72 km N Laredo. 18 April 1968. A. Chaney, *et al.* TAIC-1156(3). These three specimens are a range-margin extension in southern Texas, and may have been introduced to stock ponds (A. H. Chaney, pers. comm.).

SCAPHIOPUS BOMBIFRONS (Plains Spadefoot): JIM WELLS Co. 19.2 km SW Alice on FM 754. 7 September 1975. R. Schmidt and J. Karges. TAIC-3862(2). WILLACY Co. San Perlita. 3 May 1972. T. Blasienz. TAIC-3243.

SCAPHIOPUS COUCHI (Couch's Spadefoot): MAVERICK Co. 1.3 km E El Indio. 18 May 1978. J. Karges. TAIC-4410. 16.8 km SE Quemado. 18 May 1978. J. Karges. TAIC-4467(2).

SCAPHIOPUS HOLBROOKI HURTERI (Hurter's Spadefoot): BROOKS Co. 4.4 km W Falfurrias on TX 285. 13 March 1967. E. Martin and C. Hatch. TAIC-562. WILLACY Co. Fourteen specimens, in six series, are from various localities within the county, by several collectors. TAIC-2891, 2983(4), 2898, 2905, 2911(6).

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle): Mc CULLOCH Co. 16.5 km N Brady on US 377. 21 May 1978. J. Karges. TAIC-4396. Very few specimens have been reported from this central portion of the state.

CHRYSEMYS CONCINNA TEXANA (Texas River Cooter): LLANO Co. Lake Buchanan 6.4 km W Buchanan Dam. 13 June 1976. D. Wood.

CHRYSEMYS SCRIPTA ELEGANS (Red-eared Slider): WILLACY Co. San Perlita. 26 April 1972. P. Carrizales. TAIC-3276.

GOPHERUS BERLANDIERI (Texas Tortoise): WILLACY Co. San Perlita. 5 May 1972. R. Olivarez. TAIC-3279.

KINOSTERNON FLAVESCENS (Yellow Mud Turtle): JIM WELLS Co. 32 km NW Alice. 10 April 1964. A. H. Chaney, *et al.* TAIC-146. MAVERICK Co. 6.5 km W Eagle Pass on US 277. 19 April 1964. A. H. Chaney, *et al.* TAIC-492. WILLACY Co. Two specimens collected in April 1972 by different collectors at San Perlita. TAIC-3280, 3281.

TERRAPENE ORNATA (Western Box Turtle): NUECES Co. 14.4 km N Agua Dulce on FM 70. 26 August 1969. S. Labuda. TAIC-2018.

TRIONYX MUTICUS (Smooth Softshell): LLANO Co. Lake Buchanan, 6.4 km W Buchanan Dam. 9 June 1976. D. Wood. TAIC-4558.

TRIONYX SPINIFERUS (Spiny Softshell): KLEBERG Co. Kingsville. 23 May 1966. A. H. Chaney. TAIC-365. NUECES Co. Celanese Park, 9.6 km N Kingsville. 22 April 1965. S. Weisman. TAIC-510.

SAURIA

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner): GAINES Co. Seminole. 14 July 1967. K. Matocha and R. Zimmerman. TAIC-879(2). These specimens extend the range-margin of this species westward, from Lynn and Midland Cos.

EUMECES LATICEPS (Broadhead Skink): LAMAR Co. 6.8 km E Novice on FM 195. 24 May 1972. R. Enloe. TAIC-3170.

EUMECES TETRAGRAMMUS BREVILINEATUS (Short-lined Skink): MAVERICK Co. 3.2 km E Eagle Pass. 23 April 1971. A. Chaney, *et al.* TAIC-2473(2). I use the name *brevilineatus* as subspecific, pending publication of forthcoming taxonomic review (*fide* J.R. Dixon, pers. comm.).

HOLBROOKIA LACERATA (Spot-tailed Earless Lizard) :EDWARDS Co. 13.6 km W Rocksprings. 30 May 1973. H. Smith. TAIC-3517.

HOLBROOKIA MACULATA (Lesser Earless Lizard): GAINES Co. Seminole. 14 July 1967. K. Matocha and R. Zimmerman. TAIC-773(6).

HOLBROOKIA PROPINQUA (Keeled Earless Lizard): MAVERICK Co. 3.2 km NW Eagle Pass. 23 April 1971. A Chaney, *et al.* TAIC-2469(18). These specimens were taken farther up the Rio Grande watershed than previously reported, and represent a range extension north and westward.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard): LAMPASAS Co. 6.4 km NE Lomita. 5 October 1968. R. Zimmerman, *et al.* TAIC-1681.

UROSAURUS ORNATUS ORNATUS (Eastern Tree Lizard): MAVERICK Co. 43.2 km NW Eagle Pass on US 277. Neither date nor collector recorded. TAIC-106. 3.2 km E Eagle Pass. 23 April 1973. A. Chaney, *et al.* TAIC-2477(8).

SERPENTES

LEPTOTYPHLOPS DULCIS (Texas Blind Snake): LEE Co. 6.4 km S Giddings on US 77. 22 May 1976. J. Karges. TAIC-3943. REAL Co. 11.2 km E Vance. 2 April 1964. B. Jennings. TAIC-1932.

ARIZONA ELEGANS (Glossy Snake): COMANCHE Co. 7.3 km NE Comanche on US 377-4399. This specimen is from the central Texas hiatus mapped by Dixon and Fleet (1976).

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer): KERR Co. 20.8 km S Ker23 November 1973. A. Chaney. TAIC-3542. McCULLOCH Co. 19.6 km N Brady on US 377. 28 May 1978. J. Karges. TAIC-4414.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake): COMANCHE Co. 28.8 km NE Comanche on US 377. 28 May 1978. J. Karges.TAIC-4419.

ELAPHE OBSOLETA LINDHEIMERI (Texas Rat Snake): BEE Co. 1.6 km W Beeville on US 59. 12 May 1968. B. Simersky. TAIC-1489. LIVE OAK Co. 3.2 km N Dinero at Buckeye Knoll. 20 April 1968. B. Simersky. TAIC-1277. WHARTON Co. N Wharton. 3 July 1969. M. Simons. TAIC-236.

HYPSIGLENA TORQUATA JANI (Texas Night Snake): KLEBERG Co. 7 km W Riviera on TX 285. 23 April 1970. K. Cardwell. TAIC-2193. LA SALLE Co. 24 km SW Cotulla on FM 468. 8 April 1967. A. Chaney, *et al.* TAIC-654.

LAMPROPELTIS GETULUS SPLENDIDA (Desert Kingsnake): GOLIAD Co. 6.4 km S Goliad. 22 May 1976. J. Karges. TAIC-3939. KERR Co. 20.8 km S Kerrville. 30 March 1968. A. Chaney, *et al.* TAIC-1057. LUBBOCK Co. Lubbock. 17 May 1970. V. McDaniel and K. Matocha. TAIC-2558.

MASTICOPHIS FLAGELLUM (Coachwhip): BRISCOE Co. 16 km WSW Quitique. 4 September 1968. K. Matocha and B. Chapman. TAIC-1649. GUADALUPE Co. 23.5 km N Stockdale on TX 123. 6 August 1978. S. Parker and J. Karges. TAIC-4616. LAMAR Co. 6.8 km E Novice on FM 195. 24 May 1972. R. Enloe. TAIC-3175. MAVERICK Co. Seven specimens have been collected from different localities by several collectors. TAIC-1797, 1853(2), 2065, 3552, 3562, 3685.

NERODIA RHOMBIFERA (Diamondback Water Snake): BROOKS Co. 25.6 km W Riviera on TX 285. 23 July 1976. J. Karges and R. Schmidt. TAIC-4000. SAN JACINTO Co. 4.8 km E Pumpkin on TX 150. 22 March 1975. A. Chaney and J. Rickner. TAIC-3751. STARR Co. 4 km W Rio Grande City on US 83. 1 August 1978. J. Karges, *et al.* TAIC-4609.

OPHEODRYS AESTIVUS (Rough Green Snake): KLEBERG Co. Kingsville. 28 March 1966. B. Chapman and C. Trilica. TAIC-273. This specimen is a range-margin extension southward towards recorded localities in Cameron and Hidalgo Cos.

PITUOPHIS MELANOLEUCUS SAYI (Bullsnake): MAVERICK Co. 16 km N Eagle Pass. 27 April 1978. J. Cano, *et al.* TAIC-4356.

SALVADORA GRAHAMIAE LINEATA (Texas Patchnose Snake): DIMMITT Co. 12.5 km E Catarina. 9 April 1965. A. Chaney, *et al.* TAIC-188. DUVAL Co. 16 km S San Diego. 29 April 1978. S. Schmidt, *et al.* TAIC-4615. MAVERICK Co. 4 km N Eagle Pass on US 83. 17 April 1966. TAIC-331. 2.4 km N Quemado. 13 April 1974. A. Chaney, *et al.* TAIC-3655.

SONORA EPISCOPA (Ground Snake): JIM WELLS Co. 7.3 km W Palito Blanco on FM 735. 10 April 1964. A. Chaney, *et al.* TAIC-441. 27.2 km SSW Alice on FM 2295. 5 June 1978. R. Schmidt and J. Karges. TAIC-4362. KLEBERG Co. Sixteen specimens represent much of the county, and were collected by several collectors. TAIC-227, 443, 448, 453, 469, 501(2), 509, 630, 658, 752, 802, 989, 995, 1542, 2309.

TANTILLA ATRICEPS (Mexican Blackhead Snake): KERR Co. 20.8 km S Kerrville. 11-13 October 1968. A. Chaney, *et al.* TAIC-1657(6). WEBB Co. N Aguilares on FM 2050. 8 February 1969. J. Rickner, *et al.* TAIC-1773.

TANTILLA GRACILIS (Flathead Snake): Mc MULLEN Co. 28.8 km N Freer on FM 624. 29 March 1968. A. Chaney, *et al.* TAIC-1021(3). WEBB Co. N Aguilares on FM 2050. 8 February 1969. J. Rickner, *et al.* TAIC-1768. 19.2 km W Encinal at jct. US 83 and TX 44. 23 April 1970. A Chaney, *et al.* TAIC-2125.

TANTILLA NIGRICEPS (Plains Blackhead Snake): BROOKS Co. 6 km N Encino on US 281. 23 January 1972. D. McCarty and R. Leal. TAIC-2721. KLEBERG Co. The total of 25 specimens are from various localities within the county. TAIC-249, 458, 500(15), 593, 914(3), 931, 998, 1063, 1957. MAVERICK Co. E Eagle Pass on US 277. 17 April 1966. A. Chaney, *et al.* TAIC-334.

THAMNOPHIS MARCIANUS (Checkered Garter Snake): WILLACY Co. 6 km N Raymondville on US 77. 25 April 1972. TAIU Herpetology Class. TAIC-3089. Raymondville. 9 February 1974. T. Ortiz. TAIC-3573.

VIRGINIA STRIATULA (Rough Earth Snake): GOLIAD Co. ca. 3 km S Goliad. 10 February 1969. J. Davis, *et al.* TAIC-1755(2). Goliad. 5 March 1974. JR. Ortiz. TAIC-3581. KIMBLE Co. East Fork James River crossing of FM 385. 16 April 1972. A. Chaney, *et al.* TAIC-3190. This record is a range-margin extension southwestward from adjacent counties. NUECES Co. 6.4 km NW Corpus Christi. 15 March 1969. K. Cardwell. TAIC-1811. Corpus Christi. 11 March 1972. R. Barrera. TAIC-2927. Both of the Nueces County specimens represent range-margin extensions from adjacent San Patricio County.

MICRURUS FULVIUS TENERE (Texas Coral Snake): DIMMITT Co. 24.7 km S Catarina on US 277. 18 April 1968. A. Chaney, *et al.* TAIC-1166. Carizzo Springs. 28 April 1978. A. Chaney, *et al.* TAIC-4444.

DISTRIBUTION OF THE CHILEAN LIZARD *PRISTIDACTYLUS TORQUATUS*

The distributional range of *Pristidactylus torquatus* (Philippi, 1861) is in need of revision. Donoso-Barros (1966) published a distributional map of this lizard; however, it is a general approach and localities are not precisely noted. Donoso-Barros (1970) indicated that this species ranges from Curicó (Central Chile) to the Valdivian lakes (Southern Chile).

On the basis of 22 males, 23 females and 11 juveniles from the Zoological Museum of the Concepción University (MUZUC), 2 males and a juvenile deposited in the Herpetological Collection of the Zoology Institute of the Austral University, Valdivia (IZUA), and 16 males and 7 females from the Catholic University, Sede Talca (ICTH), a new distributional map of *P. torquatus* was contructed (Fig. 1) which was overlapped on Donoso-Barros's map. Of the localities recorded, four are new and enlarge the distributional range of *P. torquatus* to the north. Locality 1: Coihueco (Ñuble Province), 21 km (air line) SE of Chillán city (juvenile, MUZUC 5617) collected by Marquez on 21 February 1966. Locality 2: San Carlos (Ñuble Province), 22 km (by road) N of Chillán city, (juvenile, MUZUC 5604) collected by O. Felis on 25 January 1968. Locality 3: Alto Vilches (Talca Province), 1200 m, 68 km (by road) E of Talca city

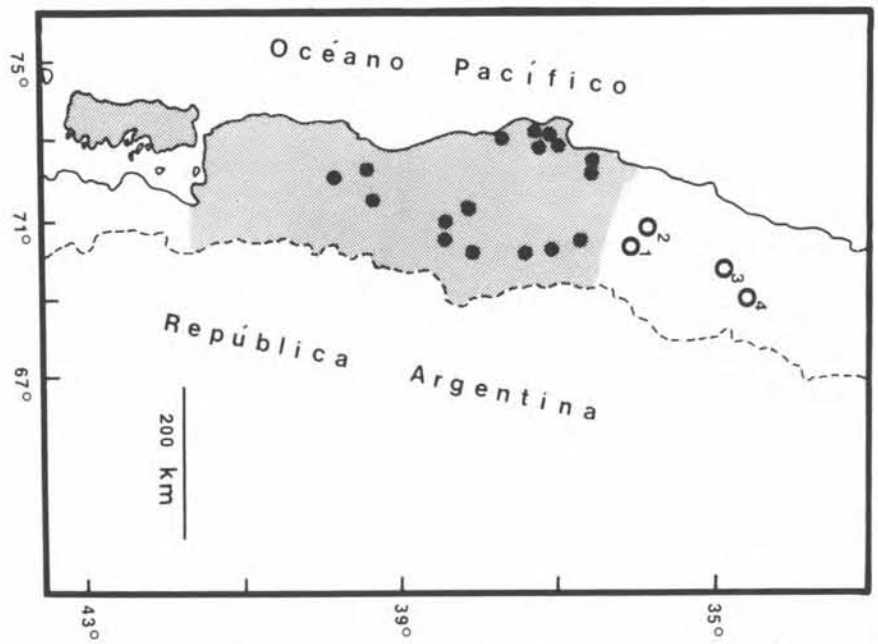

Fig. 1. *Pristidactylus torquatus* (Philippi, 1861). Open circles indicate new distributional records (numbers see text), closed circles indicate localities from which specimens were examined and Donoso-Barros's map is shaded.

(16 males; UCTH 0002-0009, 0012-0018, 0020 and 6 females; UCTH 0001, 0006, 0010, 0011, 0015, 0019) collected by R. Montecinos on November 1975 and March 1976. Locality 4: Los Queñes (Curicó Province), 42 km (air line) E of Curicó city (1 female; UCTH 0021) collected by R. Montecinos on 28 December 1976. This locality is the Northernmost locality from which *Pristidactylus torquatus* is known.

The lizards from Alto Vilches (Talca Province) were collected at a *Nothofagus* forest (*N. dombeyi, N. leoni, N glauca*). Here, the following reptiles were observed with *Pristidactylus torquatus*: *Tachymenis peruviana, Alsophis chamissonis, Liolaemus lemniscatus, L. pictus, L. tenuis,* and *L. chilensis.*

ACKNOWLEDGMENTS

We wish to thank Mr. Tomás Cekalovich, Curator of the Zoological Museum of the University of Concepción, who allowed us access to the specimens deposited in that collection.

NEWS NOTES

1980 SSAR GRANTS-IN-HERPETOLOGY DEADLINE

The Society for the Study of Amphibians and Reptiles announces the continuation of its Grants-in-Herpetology program. Four grants of at least $275. Each will be available for awarding at the SSAR annual meeting in 1980 in Milwaukee, Wisconsin. Proposals will be considered in the following areas: 1) herpetology-oriented conservation, 2) graduate student research, 3) regional society programs or projects, and 4) research in zoos.

Proposals should be typewritten (no more than five double-spaced pages) and include a statement of the problem, objectives, methods, and budget. Each applicant should have a letter of support sent by a graduate advisor, institutional or organizational officer, or another person qualified to assess their proposal. Proposals will be evaluated on the basis of appropriateness to the program, chances of success, and qualifications of the applicant by a committee comprised of Linda R. Maxson, John D. Groves, Martin J. Rosenberg, Terry Graham, and Harry W. Greene. Proposals and supporting letters should be submitted in duplicate no later than 1 April 1980 to HARRY W. GREENE, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720.

FACSIMILE REPRINTS IN HERPETOLOGY

The Society for the Study of Amphibians and Reptiles wishes to thank the following persons for their past service as members of the Editorial Committee for Facsimile Reprints:

Eddie M. Ashmore, Louisville, Kentucky (USA)
Jan Caldwell, Savannah River Ecology Laboratory (USA)
Federico Medem M., Estación de Biologîa Tropical (Colombia)
Rolande Roux-Estéve Muséum National d'Histoire Naturelle (France)
Jay M. Savage, University of Southern California (USA)

We are pleased to announce the Editorial Committee for 1979-1980:

Gordon M. Burghardt, University of Tennessee (USA)
Harold G. Cogger, Australian Museum (Australia)
J. Ramón Formas C., Universidad Austral (Chile)
Alice G. C. Grandison, British Museum (United Kingdom)
Günther Peters, Museum für Naturkunde der Humboldt-Universität (Germany)
J. D. Romer, Urban Services Department (Hong Kong).

The Committee welcomes suggestions of important papers and books that should be considered for reprinting. Details of such titles should be sent to the Editor.

Kraig Adler, Editor
Cornell University
Langmuir Laboratory
Ithaca, New York 14850 (USA)

SSAR KENNEDY AWARD

The SSAR provides for a cash award of $100 to be presented to the author of the best student paper published in each volume of the *Journal of Herpetology*. Eligible papers must be authored (or co-authored) solely by students and must be deemed worthy of the award by the Kennedy Award Committee.

Students are encouraged to be aware of the Award and to participate in the competition for it. Authors may request consideration by answering a questionnaire upon receipt of page proofs.

NOTICE TO AUTHORS PLANNING TO SUBMIT MANUSCRIPTS TO THE JOURNAL OF HERPETOLOGY

All manuscripts for the *Journal of Herpetology* should be submitted to the new editor of the *Journal:*

Rodolfo Ruibal
Journal of Herpetology
Department of Biology
University of California
Riverside, California 92521

Authors should send three (3) copies of the manuscript and all figures and illustrations should be on sheets 8½ x 11 inches.

RESEARCH REQUEST

Robert A. Young (Physiology Dept., Southern Illinois University, Carbondale, IL 62901) seeks the use of live rear-fanged snakes (especially *Boiga*). Snakes will not be harmed. Donations are preferable to loans as shipping is expensive.

Legislative Alert

LEGISLATIVE ALERT EDITOR'S NOTE:

Since the first appearance of this column in 1977 (H.R. 8(2): 37-38), I have concentrated more or less on reprinting those lists, regulations, and statutory references of U.S. federally regulated reptiles and amphibians. I will continue to provide this information; however, today over 100 treaties, international agreements, federal statutes, executive orders and federal regulations provide a complex array of interrelated and sometimes overlapping, requirements which are difficult, if not impossible, to understand. In an effort to encourage a broader understanding of the evolution and structure of the many federal laws relevant to the herpetological community, I will begin with the next issue (Herp. Rev. 11(1) to provide a brief insight into the historical, current and Constitutional underpinnings of the federal laws, court opinions, treaties and statutes which shape the present system, and some possibilities for its impovement in the future.

At this time I am soliciting *your* comments, views, ideas, etc. concerning these issues. It is my hope that this "new" approach will serve to: 1) awaken the herp community to the federal restrictions which circumscribe its activities; 2) motivate a *united* herp community to accept its responsibility to lobby and influence Congressional legislation affecting herps; and 3) serve notice to agency rulemakers that a *united* herp community demands its growing voice be heard in recognition of its own special interests and in the shaping of the future of the world's wildlife.

FINAL Rulemaking:

a) from *Federal Register*, Vol. 44, No. 174, 6 September 1979, page 51980: the special rule concerning the American alligator (*Alligator mississippiensis*) found in 50 CFR 17.42(a) has been amended to authorize the taking of alligators in the state of Louisiana in those 12 parishes in which the alligators are listed as threatened—similarity of appearance (Cameron, Vermilion, Calcasieu, Iberia, St. Mary, St. Charles, Terrebonne, Lafourche, St. Bernard, Jefferson, St. Tammany, and Plaquemines), provided that the hides of such alligators are only sold or offered for sale to persons holding a valid federal permit to buy hides issued under the special rule and the meat or other parts, except hides, of such alligators are sold only in the state of Louisiana in accordance with the laws and regulations of

that state. This rulemaking became effective 6 September 1979.

b) from *Federal Register*, Vol. 44, No. 181, 17 September 1979, page 54002: . . . the U.S. Fish and Wildlife Service recognizes that captive propagation is, in some cases, important for conserving species, and that the Endangered Species Act (as amended) authorizes the permitting of otherwise prohibited activities to enhance the propagation or survival of affected species. This rule grants general permission for persons to conduct otherwise prohibited activities with captive-bred wildlife under specified conditions, which are designed to protect wild populations of wildlife and to ensure that the activities will be conducted to enhance the propagation or survival of the species. This rulemaking (i.e., captive, self-sustaining populations) became effective on 17 September 1979.

PROPOSED Rulemaking:

a) from *Federal Register*, Vol. 44, No. 143, 24 July 1979, page 40442: the U.S. Fish and Wildlife Service now believes that the American crocodile (*Crocodylus actus*) populations outside of Florida population which was listed as Endangered on 25 Sept. 75, and the saltwater crocodile (*C. porosus*) populations exclusive of the Papua, New Guinea population to be endangered. Deadline for comments is 26 October 1979.

Send to: Director, (O.E.S.)
U.S. Fish and Wildlife Service
Department of Interior
Washington, D.C. 20240

b) from *Federal Register*, Vol. 44, No. 179, 13 September 1979, page 53422: the Fish and Wildlife Service re-proposes critical habitat for the Plymouth red-bellied turtle (*Chrysemys rubriventris bangsi*). Endangered status and critical habitat were originally proposed for this species on 19 May 1978, but the critical habitat portion of this proposal was withdrawn on 6 March 1979 because of procedural and substantive changes in the amended Endangered Species Act. Deadline for comments is 16 November 1979.

Send to: same as above

STATE-PROPOSED Rulemaking: Ohio House Bill 645—this bill will prohibit "any person owning or buying nonnative poisonous reptiles as pets, to prohibit any person from selling such reptiles except to a zoo, and to permit zoos to buy such reptiles for exhibition."

NEW DUTCH HERP GROUP

The Nederlandse Studiegroep voor Anolissen, formed about two years ago, is a subdivision of the Nederlandse Vereniging voor Herpetologie en Terrarium-kunde. Their bulletin is devoted entirely to *Anolis* articles, and is published every two months. Major articles have English summaries. The group especially welcomes articles on *Anolis* reproduction, ethology and ecology. For more information, write:

Hawaiian green turtle (*Chelonia mydas*) and monk seals (*Monachus schauinslandi*) basking on a small islet at French Frigate Shoals (23°45'N, 166°10'W). Land basking by sea turtles has only been documented for *Chelonia*, with members of the Hawaiian population possibly being the only ones at the present time exhibiting this rare behavioral trait. Hawaiian green turtles and monk seals frequently share the same beaches and inshore waters, however it is relatively uncommon for direct physical contact to take place with one another. (Photograph by George H. Balazs, Hawaii Institute of Marine Biology, P. O. Box 1346, Kaneohe, Hawaii 96744).

AVAILABLE IN 1980 -

ORDER NOW

SSAR SYMPOSIUM SERIES NO. 1

THE REPRODUCTIVE BIOLOGY AND DISEASES OF CAPTIVE REPTILES

A SYMPOSIUM

Sponsored by the Society for the Study of Amphibians and Reptiles and held at its annual meeting in June 1978 at Arizona State University, Tempe, Arizona.

Co-editors:

JAMES B. MURPHY

JOSEPH T. COLLINS

This volume contains 30 papers on a wide variety of topics involving reptilian reproduction and diseases, and clearly illuminates both the problems and the status of research in reptilian husbandry today.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

SSAR BUSINESS

SSAR TRANSLATIONS PROJECT

The object of this project is to make available to SSAR members accurate translations of foreign language research articles. Since SSAR has not budgeted money for translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy (or reprint) of the original and the translation to the editor. A few people have volunteered to translate articles, and we are interested in hearing from any others who are willing to contribute their time.

If you have an article for translation that you feel would appeal to a large segment of the herpetological community, send a copy or reprint to the editor and we will try to have it translated.

We presently have 17 articles available and have listed those available from the National Translations Center (NTC) with their current costs. For copies of the NTC articles write to: NTC, John Crerar Library, 35 West 33rd Street, Chicago, Illinois 60616. For copies of the SSAR translations include 50¢ for postage plus 5¢ per page xerox cost to the editor (address below). The number of pages of original and translation are in parentheses. New titles will be published in **Herpetological Review** as they become available.

THE NUMBERS OF AMPHIBIANS AND REPTILES

Questions frequently asked of museum or zoo curators deal with the numbers of kinds of frogs, turtles, or snakes. Usually the answers to such questions are guesses. In the course of preparing an encyclopaedic account of the living amphibians and reptiles, I tallied the numbers of recognized families and the numbers of genera and species in each.

For some large families such as Hylidae, Centrolenidae, Amphisbaenidae, Gekkonidae, Pygopodidae, Agamidae, and Chamaeleontidae, plus the turtles and crocodilians, recent checklists or reviews are available (Wermuth, 1965, 1967; Mertens, 1966; Gans, 1967; Kluge, 1976; Duellman, 1977; Wermuth and Mertens, 1977). For some groups in certain regions, recent regional catalogues were major sources of data (*e.g.*, Peters and Donoso-Barros, 1970; Peters and Orejas-Miranda, 1970; Cogger, 1975). Richard Etheridge kindly provided numbers of iguanid lizards. For many groups, data were obtained from innumerable revisions and faunal lists; many of these are out-of-date, and some present conflicting data. Therefore, some of the resulting tabulations may be highly accurate, whereas others, because of inadequate taxonomic treatment of a group or my subjectivity in selecting one arrangement over another, are open to question.

Even at the family level the classification of amphibians and reptiles is unstable (see especially Savage, 1973, versus Duellman, 1975, for families of frogs; Underwood, 1967, versus Smith, Smith and Sawin, 1977, for families of snakes). Some of these discrepancies are due to inadequate knowledge and understanding of the characters of the animals, such as the problems in snake classification. In other cases, the application of new methodologies, such as cladistics (*e.g.*, Gaffney, 1975), results in taxonomic rearrangements.

The continued rapid discovery of new species especially in tropical genera, such as *Bolitoglossa*, *Eleutherodactylus*, *Centrolenella*, and *Anolis*, seemingly makes a tabulation of the number of taxa an exercise in futility. With all of these considerations in mind, I offer the tabulations (Tables 1-2) with neither apologies nor confidence limits.

Comparisons of the North American (United States and Canada) herpetofauna based on numbers of taxa provided by Collins et al. (1978) reveals that North America has relatively diverse salamander, turtle, and snake faunas but rather poor anuran and lizard faunas (Table 3). Of the 36 families of amphibians and 46 families of reptiles in the world, 14 of amphibians and 21 of reptiles occur in North America. Similar numbers (15 and 22, respectively) inhabit South America. Personal compilations of the South American herpetofauna reveal that in comparison with North America, South America has much higher percentages of the known species of frogs and lizards, slightly more snakes, and fewer salamanders and turtles (Table 3).

I have not attempted a complete geographical analysis of the number of taxa. In addition to the data given for North and South America, a compilation of data given by Cogger (1975) reveals the presence of 155 species of amphibians and 529 species of reptiles in Australia—a total of 684 species, or 7.4 percent of the herpetofauna of the world. Australia is especially rich in lizards, with 364 species (11%) and also has a relatively large frog fauna (155 species, 6%). By comparison, North America has about 5 percent of the species of amphibians and reptiles, whereas about 24 percent occur in South America.

My figures are slightly lower than those in a list of the vertebrates of the world, dated October 1978, compiled by the National Fish and Wildlife Laboratory, Gainesville, Florida. That list has totals of 3,373 amphibians and 6,508 reptiles. Although that list apparently does contain a few recently described species not included in my tabulations, it also includes many synonyms, which seem to account for the major part of the numerical discrepancy.

TWO ABERRANT CROTALID SNAKES FROM KANSAS

Color and pattern aberrancies in crotalid snakes have been reported by Gloyd (1935, 1958), Hensley (1959), Chace and Smith (1968), Nickerson and Mays (1968), and Klauber (1972). This paper presents information on aberrancies in specimens of *Crotalus viridis viridis* and *Sistrurus catenatus tergeminus* from Kansas. The following descriptions were made from preserved specimens.

A male *Crotalus v. viridis* (KU 177024) was collected on 23 October 1977 by B. Peters 0.8 km south and 1.6 km east of Coolidge in Hamilton County, Kansas. The specimen is patternless except as noted. The dorsum is light tan with some scales having a dark brown base. The dorso-lateral scales are cream colored with flecks of gray throughout, and the venter is a uniform cream. There is no trace of pattern on the head. An irregular black band extends anteriorly on the tail *ca.* 25 mm from the base of the rattle. Gloyd (1935), and Chace and Smith (1968) reported the union of black tail rings in albinistic specimens. Scutellation is as follows: ventrals, 184; subcaudals, 25; upper labials, 15-15; lower labials, 16-16; dorsal scale rows at mid-body, 25. The rostral is noticeably enlarged. The internasals appear to be larger than normal for the species and are arranged somewhat irregularly. Gloyd (1935) commented on unusual head scalation. Snout-vent length is 89.5 cm and the tail 7.2 cm.

In March of 1972, a male *Sistrurus c. tergeminus* (KU 152341) was collected by R. Rathbon 3.2 km south and 1.6 km west of Ellsworth, Ellsworth County, Kansas. This snake has a light brown mid-dorsal stripe about three scales in width, which runs from behind the head for two-thirds the body length. This stripe is bordered on either side by a dark brownish gray stripe about two scales in width. The stripe terminates in an irregular blotch, which is followed by seven more blotches to the vent. From the vent to the tip of the tail six very faint irregular blotches are present. The ground color is dark gray, with cream dorso-lateral scales heavily flecked with brown. The venter is cream with a neavy mottling of brownish-gray, becoming progressively darker to the tip of the tail. This is apparently the first report of a striped example of the genus *Sistrurus*. Scutellation is as follows: ventrals, 146; subcaudals, 33; upper labials, 11-11; lower labials, 12-12; dorsal scale rows at mid-body, 24. The snout-length is 49.5 cm and tail length is 6.8 cm.

I thank William E. Duellman (KU) for allowing me to examine specimens in his care. Thanks also to Joseph T. Collins and Darrel Frost for their helpful suggestions. Stan Roth kindly obtained the specimen of *Crotalus viridis* and deposited it at the Museum of Natural History, University of Kansas, Lawrence (KU).

AN EARLY PUBLISHED ACCOUNT OF THE CACTUS—CORRAL MYTH

Probably most Americans with more than a casual interest in herpetology or ornithology are familiar with the story of the alleged habit of the roadrunner (*Geococcyx californianus*) of killing rattlesnakes by surrounding them with a wall of loose cactus joints. The snake, in its frantic efforts to escape from the cactus corral either fatally impales itself on the thorns or becomes so enraged that it bites itself and dies from the effects of its own venom. According to the story, the bird then either eats the snake or else immediately goes in search of another victim.

Klauber (1956) says that this still-current myth of the roadrunner's cactus corral is widespread and of respectable age. He first heard it around the campfire about 1897, but he cites earlier literature references to the story. The earliest of these is that of Heermann (1859), who recorded the tale as hearsay without indicating that he believed it. Klauber suggested that the story probably was current long before 1859.

Recently, while searching the literature preparatory to writing a biographical article on William Gambel, I found that Gambel (1849) had published an account of the roadrunner's cactus corral ten years or so prior to Heermann's account. This may well be the earliest printed reference to the myth. Actually, Gambel heard the story several years prior to publishing it.

William Gambel was a Philadelphia naturalist who was important in the early natural history exploration of the American West. He made two trips to California and died there in 1849. During his first trip, from 1841 to 1845, he travelled widely in the area, all of which at that time was part of Mexico. Sometime during his first trip he was told the cactus corral story by "Californians," by which he undoubtedly meant the native *Californios* of Spanish or Mexican descent. I think we can assume that the myth probably was current among that people well before it was related to Gambel sometime between 1841 and 1845.

Gambel's version has the roadrunner finding a sleeping snake (he says "snake" but I suspect he mainly had rattlesnakes in mind) which the bird surrounds with joints of a round-stemmed cactus. This could refer either to cholla or prickly pear, depending on whether one interprets "round-stemmed" as meaning cylindrical or flat and circular. When the corral is finished the roadrunner drops a cactus joint on the snake, which is thus rudely

awakened, and in its desperate efforts to escape from the corral, fatally injures itself on the cactus spines. Gambel, who was primarily an ornithologist and botanist, and later a physician as well (M.D., University of Pennsylvania, 1848), simply records the story in his account of the roadrunner without committing himself to either belief or disbelief, but his remarks imply that he thought it might be true. Gambel, whose name is memorialized in the lizard genus *Gambelia* as well as in the names of various other animals and plants, evidently was not a close student of snakes. Otherwise, the obvious fallacies of the cactus-corral tale would have been immediately apparent to him, or at least the fact that rattlers and some other snakes are very much at home in cactus thickets.

It is well known, of course, that roadrunners kill snakes, including rattlers, and often eat them. Klauber gives numerous instances of this and also cites a number of literature references, the earliest of which is that of Gregg (1844). However, these accounts of snake-killing by the roadrunner must be distinguished from accounts of the cactus corral.

REMARKS ON DEFENSIVE BEHAVIOR OF HOGNOSE SNAKES, *Heterodon*

Death-feigning, or letisimulation, the final stage in the defensive behavior of the snake genus *Heterodon*, has long interested naturalists. One aspect of this behavior which has aroused much speculation is the adaptive significance of the belly-up position assumed by the snakes when death-feigning. This behavior has the appearance of being nonadaptive since displaying individuals, when turned belly-down by a human, often turn belly-up again. This movement by the animal is counter to human expectations for an animal playing dead and, by inference, would seem unlikely to fool a potential predator. My observations suggest that there may be an alternative explanation for the belly-up position of supposedly death-feigning hognose snakes. In fact, "death-feigning" may be a misnomer.

Platt (1969) has reviewed the literature on death-feigning in *Heterodon*, and Gehlbach (1970) has discussed broader aspects of the same topic. Both authors agree that the series of behavioral acts terminating in death-feigning in *Heterodon* is very variable, with many steps being interchanged or omitted in the repertoire of any individual. Platt (1969) listed three phases in the defensive sequence. The first is a retreat phase which contains up to four separate acts: remaining motionless, escape, escape with jerky movements and coiling of the body and pseudo-strikes. The second phase, threatening, has three subsets: spreading neck, concealing head and psuedo-strikes. Death-feigning is the third phase; itincludes extensive defecation and discharge of the anal glands as well as hemorrhaging of the oral mucosa. During this final phase, the snake turns over on its dorsum, remaining motionless.

Observation of seven individuals of *H. platyrhinos* from Missouri, Illinois and Michigan has persuaded me that death-feigning is a logical but unappreciated consequence of the previous acts. Individual snakes encountered in the field were stimulated to begin defensive behavior by beating the adjacent ground with a stick; a series of 35 mm pictures of each animal was then taken. Snakes encountered when I was without my camera were returned to my home, where they were stimulated and photographed.

Examination of these photographic series indicated a basic defensive position not fully described by either Platt (1969) or Gehlbach (1970) although it is illustrated in Plate 7, Fig. 2 of the former publication. Under moderate levels of stimulation (roughly phase 2), the snakes frequently assume a lyre-shape (Fig. 1a). An important component of this presentation is a pseudo-head, the coiled tail, presumably acting to direct aggressive moves by the predator against a less important target. In addition, the head is enlarged by lateral broadening, and frequently feces and associated materials are discharged from the cloaca. This fecal material may be smeared on parts of the body. The lyre position can be modified, but is basically maintained. In some cases, the head and pseudo-head are in close juxtaposition (Fig. 1b); at other times the head may be hidden beneath a portion of the body so that the pseudo-head is an even more obvious target (Fig. 1c).

In phase 3, the snake rolls over on its back, but the lyre position is often maintained (Figs. 1d and 1e). In extreme cases, the head is placed close to the tail which is still coiled as a psuedo-head. Typically, the mouth is open, often with the mucal lining hemorrhaging and the tongue extended. According to my observations, there appear to be two significant adaptive features of this display. One, when the snake is in the lyre position, whether on its dorsum or venter, there is a presentation of two "heads" to a potential predator. Two,

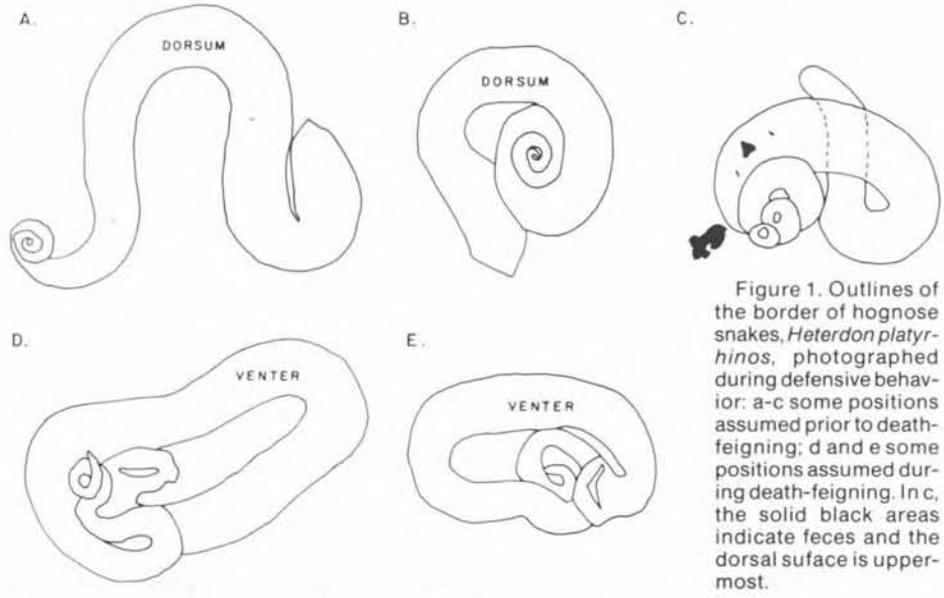

Figure 1. Outlines of the border of hognose snakes, *Heterdon platyrhinos*, photographed during defensive behavior: a-c some positions assumed prior to death-feigning; d and e some positions assumed during death-feigning. In c, the solid black areas indicate feces and the dorsal suface is uppermost.

when the snake is under the most extreme provocation and rolls over on its back, the cloaca, with its discharged feces, is displayed conspicuously next to the head and may serve as a powerful deterrent to furthur attack. The effectiveness of the fecal materials as a deterrent may be enhanced by the fact that during the display they frequently become smeared over much of the snake's body. Obviously, if my suppositions are correct, when a human or other predator flips a "death-feigning" snake over on its belly, the snake, to maximize the effectiveness of its deterrent, should roll over on its back again!

ACKNOWLEDGEMENT

I wish to thank John Pleasants for his assistance with the manuscript.

AN ELECTROMECHANICAL METHOD OF MONITORING TONGUE-FLICKERS IN SNAKES

Tongue-flicker rate has become an increasingly popular measure of arousal in snakes. It is a herpetocentric measure (Chiszar, Carter, Knight, Simonsen, & Taylor, 1976) which is useful in describing changes in activation under varying conditions. However, monitoring of tongue-flickers has been hampered by the open, unrestrained conditions under which observations have been made. Monitoring in the home cage (Burghardt, 1967; Burghardt & Pruitt, 1975; Chiszar & Radcliffe, 1976; Fuchs & Burghardt, 1971; Loop, 1970; and Sheffield, Law, & Burghardt, 1968), and in the open field apparatus (Chiszar & Carter, 1975; Chiszar, Carter, Knight, Simonsen, & Taylor, 1976; and Chiszar, Scudder, & Knight, 1976) was all done visually and recorded by hand. Studies on tongue-flicker in restrained snakes could rely upon electromechanical monitoring, which would not only increase ease of observation, but also provide a better definition of the tongue-flicker response, and probably increase reliability of the measure. The following is a description of an electromechanical procedure the authors are currently using to monitor tongue-flicker in restrained *Nerodia rhombifera*. (Fig. 1)

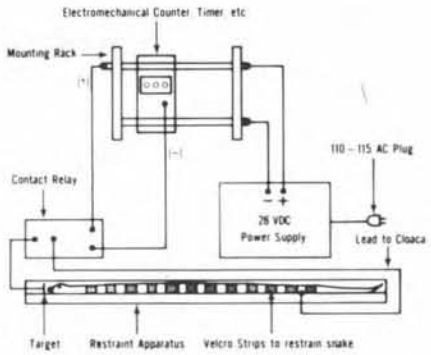

Fig. 1. Electromechanical procedure for monitoring tongue-flicker in restrained snakes.

Snakes are restrained in the apparatus described by Ward and Harrell (in press). After the animal is in place, a probe is inserted in the cloaca and taped in place using surgical tape. A metallic target is then positioned approximately ¼ inch in front of the snake's snout. The probe and the target are then connected to the input poles of the contact sensor (Scientific Prototype, drinkometer 101-K).[1] This relay is typically used to monitor lick rate in rats.

The output circuit can then be connected to a counter, timer, cumulative recorder, or other electromechanically operated device. This procedure gives an accurate record of tongue-flicker rate in the restrained snake which can be checked for reliability using visual monitoring.

In our laboratory, this procedure has been used successfully to monitor changes in tongue-flicker rate as a function of water deprivation and changes in rate when tongue-flicker is followed by water reinforcement. In the latter case, closing the contact relay pulses a water dispenser which delivers a measured amount of water via medical tubing placed directly in the snake's mouth.

LITERATURE OF THE INTERNATIONAL ZOO YEARBOOK, VOLUMES 1-18 (1959-1978)

The **INTERNATIONAL ZOO YEARBOOK (IZY)**, published by the Zoological Society of London and originating with volume 1 in 1959, was conceived with the idea of providing a source of publication for articles dealing with any subject directly related to zoo animal husbandry and captive breeding. Volumes 1-5 were published in consecutive years to 1963, then volume 6 appeared in 1966 with an annual volume appearing to date.

Each volume contains a special section devoted to a certain aspect of zoo management, and sections concerning new developments in the zoo world, exhibits and construction, zoo education, and occasionally diseases and treatments. Also in each is a census of rare animals in captivity, listings of reported captive breedings during previous years, a subject index to the previous volumes, and a listing of zoos and aquaria of the world, sometimes including staff members.

All volumes contain articles relating at least indirectly to reptiles and amphibians, although most are featured in later years. Volume 9 (1969) includes a special section devoted to herpetofauna in captivity as will volume 19 which is scheduled for publication sometime late in 1979.

This listing includes the 164 articles from volumes 1-18 (1959-1978). They are grouped in general categories with authors listed alphabetically as follows: general titles (24 articles), exhibits and construction (16), diseases and treatments (8), amphibians (7), chelonians (17), crocodilians (19), Rhynchoce-

phalia (5), saurians (28) and snakes (41). Each citation includes author(s), date, title, volume number and pagination. One article (David, 1970) dealing with the captive breeding of two taxa has been listed twice; all others have been placed in the category in which they most nearly fit.

Because of its relative expense and the fact that it is generally unavailable in most libraries, **IZY** is a reference often overlooked. In some cases, articles have included valuable behavioral observations and first published records of reproduction on various taxa. This listing will acquaint those unfamiliar with the herpetological literature published to date. Additional listings will be published for future volumes at irregular intervals.

A NEW TRAP FOR BASKING TURTLES

During the course of studies conducted at Cranberry Creek Marsh, Jefferson County, New York (Petokas, 1978), a new trap for basking turtles was designed, constructed and tested. The new trap, incorporating some of the basic designs of Lagler (1943) and Cagle (1950), was found to be an effective method of capturing basking turtles. While only painted turtles (*Chrysemys picta*) were captured, any turtle that habitually basks out of the water may be taken by this method.

The overall outside dimensions of our trap are: length, 105 cm; breadth, 73 cm; and depth, 14 cm. Traps are made from 19 x 178 mm pine planking, 127 mm aluminum flashing and 25 mm mesh chicken-wire. The planking is cut into suitable lengths to form a rectangular basking platform (Fig. 1). Each plank end is beveled so that all sides of the platform slope upwards at an angle of about 15 degrees. Wood screws and strips of scrap material (wood or metal) are used to fasten the planks at each corner. The flashing is cut into strips of suitable length, creased along the center-line and stapled to the upper surface of each plank. Lastly, a chicken-wire capture basket is stapled to the underside of the wooden platform. Urethane foam may also be added beneath the platform to adjust flotation.

The basking trap described herein may be used in any aquatic habitat having water deep enough (ca. 12-15 cm) to cover the base of the sloping platform. Our experience has been that the traps are most effective when set in beds of submerged or floating aquatic plants where few natural basking sites exist. Most turtles bask at the top of the sloping platform, and when leaving their perch often enter the trap rather than walk back down the ramp. Once inside the capture basket, turtles are deterred from climbing out of the trap by the smooth surface of the metal flashing.

The design of our trap provides several advantages over most contemporary capture methods. It is inexpensive and simple to construct, and requires no attendance except to remove captured turtles. The rectangular shape reduces the overall size and weight of the trap without decreasing its efficiency. Lastly, the trap is efficient because it captures both juveniles and adults, and because it retains most entering turtles.

ACKNOWLEDGEMENTS

We would like to thank Michael Wasielewski and Lewis Smith for their assistance during the construction of this trap and its various prototypes.

FIGURE CAPTION

Fig. 1.—Diagram of basking trap. Top view is depicted in A; cross-sectional view through a-a' is shown in B. The capture basket is represented by cross-hatching in A and the broken line in B. Heavy broken lines in A indicate a bend in the metal flashing and also demarcate the obscured inside margin of wooden planking shown by the grain pattern in A and the hatching in B. Light broken lines in the lower right-hand corner of A outline an arrow-shaped support.

HERPETOLOGY AT THE UNIVERSITY OF MICHIGAN

The University of Michigan has had a long and distinguished history of research on amphibians and reptiles and today's large numbers of faculty, staff and students with their varied interests are maintaining that tradition. On campus, the centers of activity are located in the Museum of Zoology - Alexander G. Ruthven Building, the Edward H. Kraus Natural Sciences Building, and the Amphibian Facility, and off campus, they are to be found as close as the University's E.S. George Natural History Reserve and the Douglas Lake Biological Station to as distant as Australia, Brazil, Panama and the Seychelles Islands.

Most of the herpetological activities in the Museum of Zoology are associated with the Division of Amphibians and Reptiles. The Division's curators are Arnold Kluge, Ronald Nussbaum and Donald Tinkle (also serving as Director of the Museum), and they are ably assisted by curatorial technicians Liz McGhee and Gary Breitenbach. A five-year Collection Management grant from the National Science Foundation has helped immeasurably to curate the Division's extensive collections of fluid preserved specimens, skeletons, x-rays, Kodachromes, audiotapes and frozen tissues. In addition to overall collection improvement, the Foundation's support has enabled the staff to explore new areas of curation, such as the collection and maintenance of nontraditional data (*e.g.*, genealogies, weights, ages, competition effects, color in life, and karyotypes), and to develop a computer management system of all catalog information, both traditional and nontraditional. Also housed in the Museum of Zoology is the office of the Survey of Threatened and Endangered Species of Amphibians and Reptiles of the State of Michigan which is staffed by Paul Feaver and Laurie Vitt.

The herpetological research of the Museum's staff and students includes both comparative and experimental approaches, and employs a wide variety of theories, methods and subjects as the following brief review documents. Kluge continues to develop his interest in the theory of phylogenetic inference, and he is completing a quantitative study of sphaerodactyline lizard relationships. Also, the first stage of a long-term study of sexual selection, territoriality and parental care in gladiator frogs (*Hyla boans, H. crepitans, and H. rosenbergi*), has been concluded with his fourth field season in Panama. Nussbaum has developed a major research program on caecilian biology, and he is completing a systematic study of the family Ichthyophiidae. Coupled with this primary interest he has spent considerable time in the Seychelles and Africa, and his extensive collections have led him to consider the origin and evolution of the insular herpetofaunas of the Indian Ocean, and to a reconsideration of some general theories of island biogeography. He is also involved in a long-term study of the life history and demography of the short-horned lizard (*Phrynosoma douglassi*) in Oregon. Tinkle continues to pursue a well-established program of research on life history evolution in reptiles. At present he is concentrating on very long-lived species (turtles), mainly on the George Reserve, with particular emphasis on measuring variance, over time and among ages, in life history parameters, including reproductive effort. He is also finalizing two long-term lizard field studies (one in its tenth year) that have involved considerable experimental manipulation in attempting to understand both intraspecific and interspecific competitive effects on life histories and population dynamics of lizards.

Museum postdoctoral students with herpetological research interests include Feaver and Vitt and Justin Congdon and Art Dunham. Congdon has taken a total energetics approach to understanding life histories and in particular reproductive effort. Presently, he is studying the painted turtle (*Chrysemys picta*) and four species of snakes (*Thamnophis sauritus, T. sirtalis, Nerodia sipedon* and *Coluber constrictor*) on the George Reserve and his methods include doubly-labeled water, analysis of total lipid cycles and bomb calorimetry of soma and eggs. Dunham is most interested in the structure of reptile communities, particularly desert lizards, and he emphasizes the experimental approach. He has just completed a long-term study as his Ph.D. dissertation of *Sceloporus merriami* and *Urosaurus ornatus*, which focused on environmental predictability, food, and growth rates, and he was able to rigorously test current theories of interspecific competition. Recently, Feaver completed a demographic study of the northern water snake *Nerodia sipedon* on the Geroge Reserve as his Ph.D. dissertation. He is now comparing the demography of natricine snakes, as well as summarizing information on the reproductive strategies of snakes in general. Vitt's herpetological interests include reproductive strategies of reptiles, resource partitioning in lizards, tail autotomy and other caudal adaptations in lizards, and the ecology of tropical lizards and snakes. He recently returned from a 13-month field study in the xeric region of Pernambuco, Brazil, where he accumulated considerable ecological data on several species, in cooperation with Paulo E. Vanzolini, Museu de Zoologia.

Alan Jaslow, Ed Hover, Cindy Kagarise, Scott Moody and Peter Tolson are predoctoral students in the Museum of Zoology with advanced programs of research on amphibians and reptiles. Jaslow has just returned from two years in Panama where he studied the dynamics of larval anuran communities in wet and dry seasons. In addition, he was able to study *Atelopus* reproduction and behavior, and he and Kluge have finished a detailed study of chorusing behavior and individual communication in several species of hylid frogs. Hover's thesis research concerns a color polymorphism in a New Mexico population of *Urosaurus ornatus*. He has combined studies of behavioral interactions in controlled enclosures with a field investigation of life history and social organization. Kagarise's general interests include mating systems, communication and parental care in anurans. Her thesis research centers on the reproductive biology and mating systems of *Bufo canorus* and *B. exsul*, with particular emphasis on the mating strategy of males in high density aggregations. Moody, a recent recipient of a German Academic Exchange Scholarship, is finishing his doctoral study of the phylogenetic relationships among fossil and recent agamid lizards. He has taken his data from a wide variety of systems, for example osteological and neurological, and he has analyzed these with a battery of competing phylogenetic algorithms. He has related his phylogenetic hypotheses to vicariance biogeographic theory and the facts of continental drift. Tolson is carrying out a biochemical systematic study of species in the boid snake genus *Epicrates*. He is using starch-gel electrophoresis of selected liver and muscle tissue enzymes, thin-layer and gas chromatographic/mass spectrographic analyses of the lipid secretions of the anal scent glands, and DNA-DNA hybridization. He is testing the current phylogenetic and zoogeographic hypotheses for the group.

Herpetological studies in the Natural Sciences Building are centered in the laboratories of William R. Dawson (Chairman, Division of Biological Sciences), Carl Gans and Glenn Northcutt. Dawson's interests in amphibians and reptiles primarily concern their physiological and behavioral responses to temperature. Within this area he has conducted research on aerobic and anaerobic metabolism, respiratory mechanisms, muscle physiology, water balance, ion excretion, and behavioral thermo-regulation, working primarily with lizards. His laboratory is well equipped for such studies, as well as for ones involving various biochemical procedures pertaining to analysis of body composition and determination of activity of metabolic enzymes. His current work involves analysis of thermal exchanges of the Galapagos Marine Iguana in its natural habitat. Recent research by graduate students in his laboratory has dealt with activity physiology of lizards and turtles, physiological and behavioral adaptations of *Bufo boreas* to montane situations, and effects of exercise training on metabolic capacities of *Rana pipiens*. Dawson has participated in several symposia on reptilian physiology, and he has served as Coeditor of Vol. 5A (Physiology) of the *Biology of the Reptilia*. Gans's laboratory is designed to study aspects of the functional morphology of vertebrates, with emphasis on feeding, locomotion, and breathing adaptations. He is particularly interested in the general adaptive biology of hiding or burrowing squamate reptiles. Two of Gans's graduate

students, Brian Clark and Thomas Scanlon, are studying the feeding and locomotive adaptations of a variety of reptiles. Gans is also continuing his systematic studies of amphisbaenians and uropeltid snakes. At present, Gans is a Guggenheim Fellow in Australia where, among other things, he is studying the ecology and behavior of crocodiles. He is currently editor of *The Biology of the Reptilia* and *The Journal of Morphology*, and he is president-elect of the American Society of Ichthyologists and Herpetologists. Northcutt's research concerns the evolution of vertebrate brains. He focuses on the neuroanatomical substrates underlying major behavioral adaptations, and for the present he is most interested in the neurobiological adaptations accompanying the tetrapod transition. He is a Guggenheim Fellow on sabbatical leave at the University of California, San Diego, where he is continuing his investigations of the evolution of the telencephalon of Amphibia and lung fishes. His recent research on the forebrain and midbrain organization in lizards has provided a much needed new insight into the phylogenetic relationships of this difficult group.

George Nace (Director) and Chris Richards are the senior staff members of the Amphibian Facility. The Facility's major efforts are devoted to developing genetically heterozygous strains for general research use, inbred and homozygous lines for special studies and mutant lines for specific studies. *Rana pipiens, Bombina orientalis* and *Xenopus* are the taxa of greatest concern. Richards is investigating linkage of isozyme loci, sex reversal and steroid effects, and the histocompatibility complex in *R. pipiens*. She is also continuing her research on the genetics of color dimorphism in African reed frogs of the genus *Hyperolius*.

DONALD W. PYLE

A tragic accident on the 5th of June 1979 took the life of Donald W. Pyle, Assistant Professor of Biology at Skidmore College, Saratoga Springs, New York. Don was conducting field research with me on a Timber Rattlesnake population in the Tongue Mountain region in northeastern New York when he fell from a rocky ledge.

Don Pyle was a behavioral geneticist and evolutionary biologist with a strong interest in natural history. Although not known as a herpetologist, Don rapidly became interested and deeply involved in our joint population study begun in spring 1978. Don was particularly intrigued by the selective factors involved in the maintenance of the color polymorphism of this species; this aspect of our work "bridged the gap" between field ecology and Don's strong interest in population genetics and natural selection.

Don Pyle was born in Oak Park, Illinois, on May 11, 1949. He graduated cum laude from the University of Illinois in 1971 with a bachelor's degree in biology. He received his master's and Ph.D. degrees from Arizona State University in 1972 and 1975. His doctoral work concerned the genetics of geotactic maze behavior of *Drosophila*. From 1975-1977, he did postdoctoral work at Indiana University and North Carolina State University. He published some dozen papers from 1976-1979 in genetics and behavior. His work appeared in such respected journals as American Naturalist, Genetics, Behavior Genetics, Nature, and Evolution.

Don joined the faculty of Skidmore College in the fall of 1977. He became a trusted friend and close colleague in the Biology Department, and he quickly established himself as a competent and energetic teacher, well respected by his students. This strong student concern was evidenced by their enthusiastic response to a permanent memorial award which they established in his name.

My feelings are best expressed in a statement written for Don's Memorial Service held shortly after his death:

A year and a half in the field together in the seasons of change, spring and fall, in an outdoor setting of beauty, biological diversity, and ruggedness, brought my colleague, Don Pyle, and me into harmony with each other. A harmony of thinking about nature and the selection pressures leading to what we were beginning to learn; a harmony of feeling a love and respect for the difficult terrain of our study area and its familiar slopes we forced our legs and lungs to overcome but never conquer; a harmony of accepting the routine tasks of recording data in our joint research work; and a harmony of admiration and respect for the many individual "tigers of the talus," as Don called them, whose behavior and natural history we were beginning to understand.

Our single driving oneness was to know. To know the sorts of information we sought was not going to be done quickly or easily. Our goal for June was to let four timber rattlesnakes, each "communicating" with us by surgically inserted radio transmitters, teach us what this secretive reptile does during the course of its seasonal movements. Firmly convinced that such data would touch both theory and practicality, we proceeded to set up and plan a project we felt would be scientifically productive. We melded two aspects of biological science. Don provided a theoretical framework built on his strong intellect and an acute perspective of evolutionary thinking that cut across all groups of organisms; I provided the empirical background on this particular reptilian species that currently fascinated us. Together, we felt and openly confessed that our study was a unique blend of approaches in an unusually fortunate working relationship. And another equally strong spirit characterized the past year: we became close personal friends. Our allegiance to each other was blossoming and continuing to grow.

The loss I feel from Don's tragic death is deep and severe, as it is for us all. Countless thousands of mental visions re-run the traumatic events of the difficult moments of discovery, resuscitation, and rescue of my friend. I know Don must not have suffered. His life was full and rewarding, both professionally and philosophically. He loved nature, from the western deserts to the eastern woodlands. He would never have wanted a bed with buttons, signals, and tubes. His triumph was his ability to carry out many diverse interests and to delight others with his style of thinking about the world. I benefited immeasurably from having known Don; for this I will always be grateful.

HERPETOLOGICAL HUSBANDRY

REPTILE REPRODUCTION AT THE FORT WORTH ZOO

The reptile department of the Fort Worth Zoo ended 1978 with a total of 19 varieties born or hatched during the calendar year. Of these, seven forms were new to our collection, bringing the total number of captive-bred species to well over 50 since 1971.

We were again quite successful with our crocodilian program which includes *Alligator mississipiensis*, *Caiman crocodilus yacare* and *Osteolaemus tetraspis*. Although we have had success breeding these species in previous years, 1978 was the first year that eggs and hatchlings were produced from all three in a single season (see photo).

Another significant birth involved the Malagasy ground boa, *Acrantophis dumerili*. A female on breeding loan from the Columbus Zoo copulated with one male in late November 1977. She remained off-feed until 19 July 1978 when ten young were born. As far as we have been able to determine, this is the second successful breeding of this rare boa in a United States zoo. A one-to-one sex ratio in this brood will enhance the future breeding potential of this form in both collections.

Although 19 varieties might be considered a respectable figure for a single season, this actually represents less than ten percent of the reptile species housed in the zoo's collection. With the addition of young from 1978, approximately 30 percent of our total collection has been bred in captivity here and elsewhere. It is reasonable to assume that in the near future, zoos will be forced to depend upon captive-bred stocks of reptiles as they presently do with certain species of birds and mammals; and zoos that cannot breed or otherwise obtain captive-bred specimens will see their collections dwindle or be restricted to the more common native varieties. We are currently experimenting with hibernation and related techniques which may later prove essential in the reproductive cycles of certain forms.

DECEASED ALLIGATOR SNAPPERS NEEDED

Recently deceased specimens of adult Alligator snapping turtles (*Macroclemmys temminckii*) are requested for the study of tongue musculature. Specimens should be frozen immediately upon death. Head specimens or entire bodies are acceptable. Potential donors are requested to contact: Dr. Bob Winokur, University of Nevada, Las Vegas, Department of Biological Sciences, Las Vegas, NV 89154. (702) 739-3399.

COMBAT BEHAVIOR IN THE DUSKY PYGMY RATTLESNAKE, *SISTRURUS MILIARIUS BARBOURI*, IN CAPTIVITY

Two male *Sistrurus miliarius barbouri* have been maintained in my private collection for about one year. Both snakes are from Alachua County, Florida and are maintained together in a 38 liter (10 gal.) aquarium with a paper substrate and cork bark for hiding. The temperature of the cage at the time of these observations varied between 20-27°C (the room has since been cooled down to allow for hibernation). Each snake receives a newly weaned white mouse every week or ten days.

On several occasions, I have observed combat behavior between these snakes. Such behavior has often been reported for *Crotalus* (Lowe and Norris, 1950; Shaw, 1948; Carpenter *et al.*, 1976) and for other snakes (Bogert, 1966; Lowe, 1948; Shaw, 1951; and, others), but has been reported only once in *Sistrurus* (Carpenter, In press) so I feel that my observations are worthy of note.

Each time combat was observed, it appeared to be induced by the introduction of two dead food items and was always initiated by the larger snake. Typically, the "aggressor" would approach and attempt to entwine his body about that of the other. Then, both snakes would raise the foreparts of their bodies into the air while intertwining and attempting to force each other to the ground. In the majority of cases, the larger snake was successful in forcing the smaller to the ground. The snakes were never seen to rattle or attempt to bite during combat. If they were separated to opposite corners of the cage during combat, they immediately sought each other and began again. The combat would finally end when one or both appeared to tire of it. This was usually, although not always, the smaller of the pair. After the display was completed, each would consume his mouse.

The only explanation I have for this behavior is that it is an instinctive reaction to excitement, in this case the introduction of food items. Sutherland (1958) reported food-related combat in *Crotalus horridus* and *Agkistrodon contortrix*, and the explanatory opinions of different authorities were varied. Such behavior usually falls into either the category of aggressive behavior or part of courtship activity (Carpenter, 1977). In no case has either of my snakes been so disturbed by the ritual that it refused to feed, nor has the one who appeared dominant attempted to consume both mice. Two male *Sistrurus ravus* at the Atlanta Zoo often exhibit similar behavior when being fed.

ACKNOWLEDGEMENTS

I wish to thank Scott Simpson and Tina Beasley who gave me the snakes and R. Howard Hunt for his helpful comments and advice. I thank Charles C. Carpenter for a copy of his unpublished *Sistrurus* paper and the staff of the Reptile Department, especially Dennis W. Herman, for their help.

NOTES ON CAPTIVE REPRODUCTION IN *ECHIS COLORATA* (SERPENTES: VIPERIDAE)

Palestine saw-scaled vipers (*Echis colorata*) have produced eleven clutches of eggs during the years 1971 through 1978 in the reptile collection of the Columbus Zoo, Columbus, Ohio. Seven clutches have been produced by a pair obtained from commercial sources, the male acquired 25 June 1968, and the female on 22 January 1964. Four clutches produced as a result of sibling matings between progeny of this pair hatched 3-5 August 1971.

The older pair has been maintained since 1969 in a display cage 68 x 56 x 52 cm high. The 1971 animals have been maintained since 1976 in individual cages throughout most of the year and combined into groups each spring. In 1977, they were placed in a single group of 2 males and 3 females on 14 April and were separated 30 May. In 1978, they were placed in groups of one pair and one trio of 1 male and 2 females on 28 February and were separated 1 May. Groups were housed in large aquaria of various sizes. Since 1976, all animals have been kept on a photoperiod cycle approximating that of 30 degrees N latitude.

Courtship and copulation have seldom been observed. Courtship was observed in the older pair on 7 March 1978. Copulation was observed in a pair of the 1971 animals on 19 April 1977. These behaviors were in evidence when personnel arrived in the morning and were discontinued shortly thereafter. The infrequency of the observed reproductive behavior in this form is in sharp contrast to the observed behavior of *Echis carinatus* in this collection. Specimens of *E. carinatus* which were maintained in a manner similar to that of the *E. colorata* have been frequently observed in courtship, copulation and male combat behavior throughout the day.

Dates of egg laying and hatching, clutch sizes and measurements of eggs for all clutches are given in Table 1. Eggs are smooth shelled, white and adherent immediately after oviposition. Shells are flexible and sufficiently translucent that blood vessels are often visible shortly after laying. Small, unshelled infertile masses have accompanied six clutches. The clutches laid 18 June 1973, 10 June 1977, 6 June 1978 and 21 June 1978 were each accompanied by one such mass. Two masses accompanied the clutch laid 24 June 1977, and three acompanied the clutch laid 7 June 1978.

On four occasions, females have laid a single egg of normal appearance several days prior to depositing a clutch. These occasions are summarized:

1964 female

1 egg (not measured) 13 June 1973 (clutch laid 18 June)

1 egg (38 x 25 mm) 6 June 1977 (clutch laid 10 June)

1971 female #1

1 egg (not measured) 1 June 1978 (clutch laid 7 June)

1971 female #3

1 egg (28 x 19 mm) 17 June 1978 (clutch laid 21 June)

These early eggs have not produced hatchlings and are not included in Table 1.

Eggs laid prior to 1977 were incubated in the service area of the reptile building. Temperatures were not monitored but can be reliably assumed to have frequently exceeded 32° C during incubation. Eggs laid in 1977 and 1978 were maintained in a modified commercial poultry incubator at 28° - 30° C. This change may be reflected in slightly longer incubation periods.

Prior to 1977, eggs were laid on the gravel substrate used in cages. Since 1977, gravid females have been placed in a cage with slightly damp sphagnum moss as a substrate prior to egg laying, and all clutches have been laid on that substrate. This change may be involved in an increase in the size of the eggs, particularly the short axis, since that time.

One egg from the 6 June 1978 clutch produced twins, attached to a single yolk within the egg. An egg from the 10 June 1977 clutch, opened four days after the remainder of the clutch had hatched, contained a dead, fully formed 183 mm snake. The snake had not cut the eggshell, and was found with one fang and the opposing teeth of the lower jaw deeply imbedded in its body near the base of the tail.

Hatchlings have shed 8 - 12 days after leaving eggs. The behavior, characteristic of the genus, of rubbing the obliquely keeled scales of one portion of the body against those of another portion, has been observed within two days after hatching, although sound produced by hatchlings was not audible at a distance of approximately 300 mm. Hatchlings have begun feeding on newborn mice at intervals varying from within one week after the first shedding up to fourteen weeks. In contrast to newborn *E. carinatus*, none of the hatchling *E. colorata* has fed on crickets. Young of both taxa have fed more readily when maintained at temperatures above 27° C. Feeding behavior of hatchlings appears similar to that of adults. Prey is usually struck from less than 1/3 the body length of the snake, and gripped tightly in the jaws for one to four minutes. Sufficient force is exerted to noticeably deform the shape of the prey. Often the body of the snake will be tensed and rotated on the longitudinal axis during prey seizure. In most cases, prey is not released before swallowing.

Viable *E. colorata* hatchlings have varied from 181 to 218 mm total length, with most being 195 - 215 mm. Those which have begun feeding on a regular basis shortly after hatching have reached 260 - 285 mm total length in their first year, and 350 - 380 mm total length in their second year.

Both males and females of the 1971 clutch were capable of producing viable young in their fifth year. At the time of her first egg laying, female number 5 was the smallest individual of the 1971 snakes, at 574 mm total length. An additional 1971 female, 613 mm total length, contained eleven oviducal eggs, 11 - 14 mm in diameter, when killed by a bite from a littermate 14 April 1977.

The age of the 1964 female is noteworthy, as it is currently listed by Bowler (1977) as the longevity record for the taxon. Although exact age cannot be determined, it was approximately 295 mm on 22 January 1964. This would correspond to growth of the most rapidly growing second year young produced in this collection. Thus, it was at least in its fifteenth year when the 1978 clutch was laid, but no reduction in reproductive capability has yet occurred.

All data prior to 1976 were collected and maintained by the late Louis J. Pistoia, Curator of Reptiles at the Columbus Zoo until his death in May, 1976.

BOOK REVIEWS

THE SAND LIZARD, LACERTA AGILIS. Edited by A. Jablokov. Pritkaja Jascherica Government Publishing House, "Nauka Science" Moscow. 1976. 376 pp.

This is the first Russian monograph about all aspects of the biology of one lizard species. *Lacerta agilis* is a common European species, and has an important role in its biocenosis. The authors — 36 specialists — thoroughly review the biology of *L. agilis*, and it is clear that though a well known, common species, much remains to be learned by studying this "known" animal through new, more detailed, high level methods. The authors use materials from Russian and European collections, literature, and results of their own research. The general editor for this book is Dr. A. Jablokov; it contains works done at the Institute of Biology of Development and Institute of Evolutional Morphology and Ecology of Animals (Academy of Sciences of USSR, Moscow). The specialists at these institutes are interested in *L. agilis* as a common model for studying evolution of species, especially evolutionary processes in one species and the role of various factors in selection, isolation, etc. However, the amount of general research presented on aspects of ecology and evolutionary problems is relatively small.

Chapters are: 1) Range and Habitat by N. Scherback and N. Ostashko — includes known range of *L. agilis* based on museum collections. The range is satisfactorily studied in the USSR (except for the eastern areas) and northwest Europe, but is poorly known in China, France and Yugoslavia. The authors exclude from the range of *L. agilis* Spain and nearby parts of France, but Alfredo Salvador includes *L. agilis* in the herpetofauna of Spain in local isolated areas of the Pyrenees (see A. Salvador "Guia de los Anfibios y Reptiles Espanoles" Madrid, 1974). Among the factors affecting *L. agilis's* existence is an anthropogenic one, in that increased human activity (urbanization) limited the populations of *L. agilis* in Europe, while some different changes of natural habitats in USSR (artificial forests, roads and fields) can support lizard populations. This factor needs special attention in new research and conservation activity. The readers of this book would profit from a more detailed discussion of historical factors affecting distribution and existence of *L. agilis*.

Chapter 2: Systematics by I. Darevsky, N. Scherback, and G. Peters - This chapter discusses in detail the characteristics of *L. agilis* subspecies based on 3658 measured specimens and diagnoses 9 subspecies as follows: Eastern group: *L. a. grusinica* Peters, 1960; *L. a. boemica* Suchov, 1929; *L. a. brevicaudata* Peters, 1958; *L. a. iorensis* Peters and Muskhelischiwili, 1968; *L. a. exigua* (Eichwald, 1830); Western group: *L. a. agilis* Linnaeus, 1758; *L. a. chersonensis* Andrzejowski, 1832; L. a. euxinica Fuhn and Vancea, 1964; *L. a. bosnica* Schreiber, 1912. According to the authors, *L. agilis* evolved in the Caucasian region. The variability of *L. agilis* shows that divergence of forms continues yet, especially among eastern subspecies; the forms from Siberia need further study as they are really different from the nominate subspecies, especially in some isolated populations in montane Siberian areas (Altaj, East Sajan, etc.). The problems of variability and subspecies status are summarized in this chapter, and may be useful for development of new investigations.

Chapter 3: Morphology by A. Baranov, A. Valecky, A. Jablokov — This chapter is generally based on earlier investigation, and summarizes known literature in this field, particularly Russian. It contains information about size, skin structure, coloration, and discusses subspecies whose origin is based on color aberrations (*erythronotus, rubra, immaculata, punctata, nigra*) according to investigations of authors. The description of skeleton, muscles, respiration, blood systems, sensory structures and internal systems are not new and are relatively short, reflecting little new research in these fields, especially in nervous systems, internal organization of lizard anatomy and physiology.

Chapter 4: Physiology and biochemistry by J. Antipchuck and L. Smelkovsky — This chapter is like chapter 3 in level of investigation, and summarizes known information on this field. The authors frequently use information about other reptilians as analogy to *L. agilis* in discussing processes of respiration, thermoregulation and other physiological functions. This chapter contains previously unpublished information about trace element concentrations in *L. agilis* collected by L. Smelkovsky. This chapter shows how little is known about physiology and biochemistry of *L. agilis* today.

Chapter 5: Environmental habitats by M. Tertishnikov — This chapter describes various environmental factors: types of biotopes, including natural and cultural biotypes; lizards' selection of various biotopes; wintering; humidity; affects of agriculture; soils; illumination; territoriality; and types of burrows. This chapter is based on earlier authors' research and summarizes known Russian literature. This material shows only behavior of lizards in nature, and excludes experimental observation about biotopic selection by lizards, territoriality, diel activity, and seasonality.

Chapter 6: Feeding by G. Lukina — It is a very detailed summary of literature, particularly Russian, about this aspect, including food type, quantity, predation strategy, seasonality and annuality of food species, plus variations by biotopes, sexes, sizes, etc.

Chapter 7: Breeding by A. Baranov, A. Strelcov, M. Tertishnikov — This chapter only reviews early known information on breeding of *L. agilis*.

Chapter 8: Development and growth by F. Danieljan, A. Simojan, A. Jablokov and E. Smirina — This chapter contains original observations and laboratory experiments by the authors on embryonal/post-embryonal development, eggs, and incubation. It discusses the problem of identification of *L. agilis* age groups by various methods. According to Smirina, the identification of age is possible by skeletal characteristics.

Chapter 9: Movement and Migration by M. Tertishnikov — Detailed description of early authors' investigations is presented with an analysis of Russian literature, but some aspects of migration are fragmental and need more experimental study.

Chapter 10: Behavior and Activity by M. Tertishnikov — This chapter discusses the early known information about some aspects of lizards' natural activity — seasonality, diel activity, and some aspects of behavior (especially breeding behavior) — known from Russian investigations. There are detailed descriptions of drinking and burrowing, but some important problems of behavior are not thoroughly discussed (for example, social behavior, aggression, territorial behavior). This is the result of little Russian research in ethology, and little information about behavior of *L. agilis* from western Europe. However, the authors show that *L. agilis* has relatively complicated behavior that may be changing. The discussion of lizard behavior in captivity is comparatively short; however, the few observations may be very useful for understanding lizard behaviorisms and their variability. For example, the book doesn't note anything about lizard learning, but the research of I. Beritashwili can contribute some notes about functions and possible characteristics of lizard learning.

Chapter 11: Population Structure by A. Jablokov - The author discusses the literature about *L. agilis* populations. The population structure is relatively complicated and varies in different parts of the range.

Chapter 12: Parasites by V. Sharpilo and L. Schur - In this chapter, the authors cite known parasites collected from *L. agilis*, but do not treat the affects of this parasitism. Dermal tumors (Papillomata) in *L. agilis* are described (see H. Reichenback-Klinke and E. Elkan *Diseases of Reptiles*. 1971. TFH, Inc. publication).

Chapter 13: *L. agilis* as consumer and producer by M. Tertishnikov - It is a theoretical chapter of *L. agilis's* part in its biocenosis.

Chapter 14: Population dynamics by A. Baranov and A. Jablokov and, Chapter 15: Biomass by A. Jablokov and M. Tertishnikov -These chapters include a summary of literature about lizard abundance, method of calculation, relative number of *L. agilis* in various biotopes, and the dynamics of various populations.

Chapter 16: Practical Importance by N. Scherback, M. Tertishnikov, V. Kotljarevskaja, V. Sharpilo, A. Audrushko - This chapter analyzes the economic role of *L. agilis*. It is deemed very useful in agricultural settings as a consumer of harmful insects. *L. agilis* is cheaper to use and easier than chemicals according to the authors' calculations.

The management of *L. agilis* artificial populations relies upon continued introduction.

Generally, this book is very useful for various specialists as a summary of known material about *L. agilis* and to underscore problems in need of detailed investigation. For example, it identifies as an important factor in *L. agilis's* life history "Homo scientificus" (collectors who kill many lizards for research and experiments), a new problem in *L. agilis's* conservation. This book will provide a high-standard compendium for many years, but a very limited circulation which stopped wide distribution of this book will hamper its utility. The book is especially rare in western Europe, a major part of *L. agilis's* range. It is hoped that updated editions of this monograph will be prepared as time goes on. For example, not included in this edition is a very interesting description of a captive breeding colony of *L. agilis*. It is briefly noted by the authors. Soviet herpetologists are now planning the production of new monographs about *Rana terrestris, Eremias, Hynobius,* etc., and this first monograph may be a very useful model in writing this type of book.

The excellent cooperation among the several authors results in inclusion of many new unpublished details about *L. agilis* from their own observations, plus early research that increases the value of this book as a new, original monograph in world herpetology. It is well written and easily understandable for both specialists and any others interested in aspects of *L. agilis's* biology.

IDENTIFICATION MANUAL TO THE AMPHIBIANS AND REPTILES OF FLORIDA, by Ray E. Ashton, Jr. Florida State Museum Interpretation Series, no. 1. 1978. Price $2.00 + .50 postage (4% sales tax to Fla. addresses).

Like its Kansas progenitor (Karns, *et al.* 1974), this guide is intended to make identification of a regional herpetofauna as painless as possible for novices. It accomplishes this objective via a series of easily followed flow charts identical to those developed and tested for the Kansas guide (nothing succeeds like success). One hundred thirty-four taxa are presented with very few snafus. The hognose snake reversal ("Snake" page 18) has been corrected. Amusingly, the Kansas guide has a similarly corrected error in the same genus — emulation can go too far! The Green Water Snake block ("Snake" page 19) remains titled only "Water Snake." The drawings provide adequate aid to final identification of most forms, though they are of slight utility in distinguishing similarly patterned, related taxa and several small snakes. The guide to use of the charts is concise and well written. The species list preceding the charts is a handy addition, though it might more logically have followed the charts, providing information on a species after identification.

Like the Kansas guide, the booklet is not continuously paginated. This, plus a brief table of contents to major sections would add materially to its utility. The section references in the general vertebrate chart necessitate a good deal of undirected page flipping.

The introductory pages showed disappointingly little editorial attention. Hence, numerous errors of grammar and structure persist. J. C. Dickinson, Jr. appears at first glance to be one of the artists — sort of a drop from being museum director. A sentence in paragraph 3 of the section on reptile maintenance could easily be interpreted by novices as distinguishing crickets and mealworms from insects. Several punctuation marks are misused and others are missing. External fertilization of anurans is described, closely followed by the statement "Salamanders reproduce in a similar fashion. . ." Too bad about all those years wasted evolving spermatophores. Newts are described as possessing a " . . . thicker, warty skin . . .", though this only applies to the eft stage of *Notophthalmus* development.

Despite its shortcomings, which hopefully will be corrected in future printings, this booklet will be a worthwhile purchase for those novices desiring a quick identification reference to the Florida herpetofauna. It should prove similarly handy for class use in schools and nature camps. It is a good "stepping-stone" to more detailed herpetological references.

INTRODUCTION TO HERPETOLOGY, 3rd EDITION, by Coleman J. Goin, Olive B. Goin and George R. Zug. 1978, 378 pages. $15.95. Witt, Freeman and Company, San Francisco.

This book shows considerable improvement its third time around. As stated in the preface, much reorganization is evident, especially in the chapters covering paleontology, reptilian reproduction, homeostasis, environmental relations, speciation and distribution. Many figures through the first half of the book are retained from the second edition but several have been redrawn to enhance clarity (notably 5-3 and 11-4 (the former 12-1)). A number of new figures enhance the clarity of the presentation, though most new ones mentioned in the publisher's literature are in the last third of the book (the taxonomic accounts).

The quality of the paper (glare white vs. off-white) and the lighter printing selected with this type font makes the third edition a more difficult volume to read than the second. Also, the chapter on reptilian reproduction would have been enhanced by the incorporation of Atlanta Zoo's very interesting documentation of elaborate parental care in Morelet's crocodiles. As it stands, the chapter retains sparce information (some of it conjectural) on the breeding habits of American alligators. The majority of the reference sections following chapters have been updated with well-selected new material, and offer the beginning herp student a good base from which to explore the content of most chapters further.

Chapter 12 begins the feature of this book which I had fervently hoped would be pitched from the new edition. Thirty-eight percent of the volume consists of taxonomic accounts of the living orders of herps, and presents capsule descriptions of taxa down to (in many cases) subfamilial level. Because of the necessary brevity of coverage, much of the taxonomic material takes on the nature of a trivia contest. The fact that *"Batrachuperus* differs from both *Hynobius* and *Pachypalaminus* in having the vomerine teeth separated into two small, isolated patches, rather than in a V-shaped series" is apt to be of little value or interest to a new student of herpetology using this introductory text. If this difference in dentition could be attributed to differences in feeding behavior, then *that* would be interesting, stimulating reading. Much interesting material on anatomy, physiology, general ecology and, especially, reproductive behavior of herps is entombed in this section (cost-wise, it amounts to a little more than $6.00 of the book's $15.95 price). I feel the book would be improved by retaining the taxonomic presentation as a simple table, including a new chapter covering major anatomical features unique to the living orders of herps, and redistributing the remaining material to appropriate chapters (expanding on some of the odder, more fascinating things which herps do). This last recommendation would serve to eliminate the dry, overly "clipped" appearance of a number of sections within chapters.

The book is generally free of typographical errors. I only noted two: on page 98, ovoviviparity is lacking the "t"; on page 113, the statement is made that Liebespeil precedes *courtship* instead of *copulation*. There are probably a few others, but they did not leap out at me and I was not attempting to sieve them all out. The index is generally satisfactory, though a few terms which a novice might hear and seek to identify are not listed; a thorough glossary might be a handy addition to future versions.

THE BIOLOGY OF AN EQUATORIAL HERPETOFAUNA IN AMAZONIAN ECUADOR, By William E. Duellman. The University of Kansas Museum of Natural History Miscellaneous Publication, number 65, pp. 1-352, figures 1-198, tables 1-34, plates (in color) 1-4. $15.00 (paper).

Duellman's most recent major work represents the culmination of a decade of field work by the author and most of his stu-

dents in the upper Amazon Basin in eastern Ecuador. As in his earlier monographic studies, most of the taxonomic considerations were presented in short papers prior to the publication of the summary. A few taxonomic alterations are included in this work.

The publication consists of six 'chapters.' The first reports the scope and methods of the study as well as describes the study area (essentially the immediate environment of an airstrip then called Santa Cecilia), a site in the aseasonal rainforests just east of the Andes in northern Ecuador. Material is reported from five localities lying along the Rio Aguarico separated by a distance of some 120 kilometers.

The second 'chapter' provides keys to the identification of the 185 species making up the herpetofauna as well as keys to the known tadpoles. The keys are given in both English and Spanish. Their utility is enhanced by many drawings illustrating qualitative character-states. Further aid to identification is found in the 185 species accounts and the illustrations of individuals (photographs of 2 salamanders, 64 frogs, 22 lizards, 29 snakes and color paintings of 15 frogs, 6 lizards, and 8 snakes; 146 of the 185 species). Most of the photographs are of reasonable or high quality but several should probably not have been included because they are of lesser quality than most.

The third 'chapter' (187 pages of the text) is given to the 185 species accounts wherein are provided comparative paragraph(s) on identification, a statement on occurrence (ecological), life history data, food, and, where appropriate, descriptions of mating calls and tadpoles. A pleasant component of this chapter is the presence of four color plates (2 of frogs, one of anoles, and one of snakes) rendered by Linda Trueb, the competent editor of the volume.

The fourth 'chapter' reviews data on reproductive biologies of the herpetofauna. Frogs are discussed in considerable detail and Duellman's account largely readdresses material presented earlier by Crump (1974) and Salthe and Duellman (1973). Lizards and snakes are also treated at some length augmenting studies by Dixon and Soini (1975, 1976) and Fitch (1970). The paucity of information on caecilians, salamanders, turtles, and crocodilians reflects the interests, activity cycles, and collecting skills of Duellman and a generation of Kansas students as much as anything else.

The fifth 'chapter' addresses community structure. Duellman concludes that resources are not limiting and that niche overlap is high. The nature of his study and the competing demands of documenting the fauna relegated efforts to study community structure to a relatively low priority. Duellman notes these inadequacies but nonetheless attempts a series of analyses within the constraints of his biased data sets.

The last 'chapter' consists of a biogeographic summary for the herpetofauna. Duellman suggests that there are 8 distributional patterns exhibited by the 185 species. The evolution of the herpetofauna is presented within the frameworks of Haffer's (1969) and Savage's (1966, 1973) models.

The study is the most complete produced to date for any Neotropical herpetofauna. A similar study has not been produced for even Barro Colorado Island in Panama. The taxonomy employed is more or less up-to-date although Duellman's failure to use *Ololygon* for the *Hyla* of the *rubra* Group or to use *Vanzolinius* for *Leptodactylus discodactylus* (or to explain why he didn't use these) is inexplicable and vexing. The text is remarkably error free (I noted only a few trivial spelling errors). The only substantive error I caught is that Figure 56 is an excellent photograph of *Eleutherodactylus rubicundus* (Jiménez de la Espada), but not *E. diadematus* (Jiménez de la Espada). Neither species has been illustrated previously but *E. rubicundus* does not occur in the fauna Duellman reports. However, I suspect that this error is likely to bother only Duellman and me.

Duellman reports 185 species for the Santa Cecilia area (94 amphibians and 91 reptiles) but only 172 (86 amphibians and 86 reptiles) from the primary study site (Santa Cecilia). He confidently predicts that no more' . . . than ten additional species (mostly snakes) might be found in the area.' Such confidence is probably over-extended. Two caecilians, six frogs, two lizards, and three snakes included in the 185 species were not found at Santa Cecilia in 48 man months of fieldwork and one caecilian, three frogs, one turtle, three lizards, and eight snakes are each represented by single individuals from Santa Cecilia. These 29 species comprise a substantial percentage of the fauna. I would guess Duellman's underestimate is greater than 10 species, possibly on the order of 20 or 30 species.

Duellman's epilogue (a luxury always tolerated in so large a study) outlines how he would do the study could he start over. Certainly his experience warrants such suggestions but one wonders if the epilogue would not have been more appropriate in Spanish. A note of sadness for those of us who worked (however briefly) at Santa Cecilia is Duellman's closing paragraph —that the place from whence came these observations and 8000 + specimens is no more.

Most students of the Neotropics will find this study invaluable. Its reasonable price and quality recommend if for anyone interested in herpetology and/or a description of a piece of the severely pressed and rapidly vanishing *terra incognita*. Bill Duellman deserves our thanks for a job well done.

DIETARY ADAPTATIONS IN ANIMALS by J. L. Cloudsley-Thompson. 1976. Meadowfield Press Ltd. (Dale Rd. Industrial Estate, Shildon, Co. Durham. DL4 2QZ, England). $7.00 (U.S.). 70 pp.

Part of the publisher's "Patterns of Progress" series, this booklet is based upon a similar chapter in Pergamon Press's **International Encyclopedia of Food and Nutrition** (1972). Removed from the context of the larger work, the booklet is something of a disappointment. To review in any meaningful fashion the dietary adaptations present in the entire animal kingdom in 70 illustrated pages means *a priori* that the work is going to be sketchy. This it is; too sketchy for research or graduate teaching use, too costly ($7.00 for one life function is a bit high) for undergraduate class use, and yet not exactly what one would seek for "light reading."

The references cited are adequate, though in the four years between the appearance of the parent chapter and the booklet, new material has appeared which should have been added. For example, beyond birds merely possessing a sense of smell (p. 2-36), this capacity is quite well developed in certain vulture species. Mucous-trap filter feeding (p. 2-8) is known in larval amphibians, and need not be a "primitive chordate feeding mechanism" as suggested.

Vampire bats are listed as "blood suckers" in several places, despite a correct description of their shave-and-lap behavior in the same section. This is disheartening. The photo of "*Crotalus atrox*" on page 2-35 is not *atrox* or even close to it (it might be *Crotalus cerastes*). Quality of printing is rather poor, and all-in-all I find little in this booklet to recommend it. If you find one in a garage sale for 25 cents and wish to spend about 3 hours surveying animal feeding, it would be a good purchase. But, not for $7.00. I am left wondering why the author, a very competent and respected zoologist, allowed the publisher to market this with his name on it.

EARLY HERPETOLOGICAL STUDIES AND SURVEYS IN THE EASTERN UNITED STATES. Edited with an introduction by Kraig Adler. 1978. Arno Press, New York. A facsimile reprint of 18 studies. Pagination indeterminate (**ca.** one inch thick). $40.00.

For herpetologists who have spent years (even decades) searching musty used-book stores for the early literature on North American amphibians and reptiles, and who have watched the prices of these works spiral so high as to exceed the recent increase in energy costs, this tidy volume is a welcome treasure. Adler has carefully compiled an interesting and useful array of studies and surveys by eighteen naturalists whose early observations formed an invaluable record of biological exploration of our nation during the eighteenth and nineteenth centuries.

As in any compilation by different authors on diverse topics, this book is a conglomeration. The four papers by Richard Harlan represent a useful unit for quick reference to his most important works, but the reader will need a good memory to recall each of the other authors contained therein, and may neglect to consult this volume as a main source for them. This, however, in no way negates the simple value of having these works now available at a reasonable price. The inclusion of Hans Sloane's fanciful 1734 work on rattlesnakes is of dubious value to biologists, but provides some levity as well as a view of eighteenth century prose. I find the lack of overall sequential pagination annoying since it requires a bit of searching for a specific author. This, unfortunately, seems to be the trend with facsimiles of collected works.

I am pleased that Arno Press has undertaken such an ambitious facsimile program, and I feel this represents a good contribution in such a series. For North American herpetologists, it is a necessary addition to their library.

LEGISLATION

LEGISLATIVE ALERT

FINAL Rulemaking:

a) from *Federal Register*, Vol. 44, No. 75, 17 April 1979, page 23062: The U.S.F. & W. Service has determined that the Bolson tortoise (*Gopherus flavomarginatus*) is an *Endangered* species. This rulemaking became effective 17 May 1979.

b) from *Federal Register*, Vol. 44, No. 85, 1 May 1979, page 25483: The following reptiles have received status changes on the CITES Appendices:
Gopherus flavomarginatus Bolson tortoise—change to Appendix I
Alligator mississippiensis American alligator—change to Appendix II
Crocodylus acutus (U.S. population) American crocodile—change to Appendix I
Crocodylus porosus (except saltwater crocodile, Papua, New Guinea population)—change to Appendix I
—effective 28 Jun 1979

PROPOSED Rulemaking:

a) from *Federal Register*, Vol. 44, No. 99, 21 May 1979, page 29566: The Endangered Species Act of 1973 (as amended) requires the U.S. Fish and Wildlife Service to conduct a status review of all listed species at least once every five years. Fish and Wildlife is requesting comments and appropriate data from any party which could potentially alter the status for the selected species of endangered or threatened wildlife. Deadline for comments: 20 August 1979.
Send to: Director, Fish and Wildlife Service
Federal Wildlife Permit Office
Washington, D.C. 20240

b) from *Federal Register*, Vol. 44, No. 101, 23 May 1979, page 30044; The Fish and Wildlife Service proposes to grant general permission to the public to take, engage in interstate and foreign commerce, and conduct certain other prohibited activities with captive-bred Endangered and Threatened species. Such permission would be limited to activities conducted to enhance the propogation or survival of the affected species. It also would be limited to exotic species and those native species that are sufficiently protected in the wild. Persons operating under these rules would be required to register and report on activities to the Fish and Wildlife Service so that a necessary minimum level of control can be maintained. Deadline for comments: 23 July 1979.
Send to: Director, Fish and Wildlife Service
Federal Wildlife Permit Office
Washington, D.C. 20240

c) from *Federal Register*, Vol. 44, No. 106, 31 May 1979, page 31534: The Endangered Species Scientific Authority (ESSA) is seeking public comment in order to determine whether commercial export of American alligator hides harvested after June 28, 1979 will not be detrimental to the survival of the alligator or other crocodilian species. Federal export permits could be issued only for hides that were harvested in Louisiana and Florida subject to specified conditions. Deadline for comments: 30 July 1979.
Send to: Executive Secretary, ESSA
18th and C Streets, NW
Washington, D.C. 20240

d) from *Federal Register*, Vol. 44, No. 112, 8 June 1979, page 33127: These regulations describe the functions and procedures of Endangered Species review boards and the Endangered Species Committee under the Endangered Species Act of 1973 (as amended), 16 U.S.C. 1531 *et seq*. These rules cover the exemption application processing period from the appointment of a review board to the final committee's determination. Deadline for comments: 4 September 1979.
Send to: Chairman, Endangered Species Committee
c/o Office of Policy Analysis
Department of the Interior
18th and C Streets, NW
Washington, D.C. 20240

LIZARDS, LAWS, AND LITIGATION

One of the most frustrating problems facing herpetologists, as well as other biologists today, is the profusion of state, federal, and international regulations concerning the collection, transportation, exportation, and importation of plants and animals. Many of us, either intentionally or unintentionally, have acquired material illegally, and some of us have faced litigation.

In 1975 I imported seven specimens of non-endangered lizards into the United States without proper permits. In May 1978, agents from the U.S. Fish and Wildlife Service, acting on an "anonymous tip," approached me about the specimens. A deposition was taken, and the specimens were seized. Shortly thereafter I obtained *ex post facto* permission from the country of export (Ecuador). In October 1978 I was informed that I had violated the Lacey Act and was assessed a civil penalty of $100. This was paid, and the proceedings were terminated. Throughout the proceedings I cooperated fully with the personnel of the U.S. Fish and Wildlife Service, who were courteous and efficient.

The days of the casual collecting trip are over. Collection and acquistion of specimens must be planned for well in advance (applications for collecting permits for some countries must be submitted six months prior to the initiation of field work). Probably the most frustrating aspect of obtaining necessary permits is the inevitable delays and bureaucratic red tape; fortunately, in many foreign countries, sympathetic colleagues or government officials can and will expedite the issuance of permits. Many so-called third world countries are becoming increasingly aware of their natural resources and are taking steps to establish research collections. It behooves the scientific collector to work with scientists and agencies in these countries by depositing parts of their collections there, assisting in the proper identification of specimens, exchanging specimens for study, and providing needed literature. Such cooperation

on a personal basis is the first step in the implementation of realistic scientific affiliation that can benefit our science.

HOUSTON TOAD RECOVERY TEAM MEETS IN HOUSTON

The first meeting of the Houston Toad Recovery Team was held in Houston, Texas on January 18 and 19, 1979. The Team was appointed in 1978 by Lynn A. Greenwalt, Director of the U.S. Fish and Wildlife Service. Members include: Floyd E. Potter, Leader, Texas Parks and Wildlife Department; Lauren E. Brown, Illinois State University; William L. McClure, Texas Department of Highways and Public Transportation; Norman J. Scott, National Fish and Wildlife Laboratory, University of New Mexico; and Robert A. Thomas, Louisiana Nature Center. One of the major responsibilites of the Team is the development of a Recovery Plan for the endangered Houston toad (*Bufo houstonensis*). Since the early 1950's, the expansion of the city of Houston was one of the important factors which resulted in the near-extinction of this species. In 1977, Critical Habitat was suggested for the species in natural areas in and around the city of Houston. National press and television coverage was given to the stiff opposition to these plans by the construction industry, businesses, and land developers. Consequently, the Houston toad has become well-known as a symbol of the plight of endangered species suffering from the expansion of cities.

The Team visited the type locality of the species and surrounding areas to observe the devastating habitat destruction which has occurred in recent years. A possible refuge was also inspected. The Team heard reports given by Barry Hinderstein (Texas Southern Univer-sity) on the current status of the Houston toad in Harris County, and by Hugh Quinn (Houston Zoo) on the rearing of Houston toads in captivity. James E. Johnson (U.S. Fish and Wildlife Service) led a discussion on the duties of the Recovery Team, the legal and political ramifications of the assignment of Critical Habitat in Harris County, and the format for the Recovery Plan. After the meeting was adjourned, the Team visited the Houston Zoo to observe the propagation and rearing facilities that have been developed for the Houston toad. The next meeting will be scheduled for sometime in the spring.

INTERIM REPORT ON THE COMPILATION OF A STANDARD LIST OF COMMON NAMES FOR A FIELD GUIDE TO MEXICAN AMPHIBIANS AND REPTILES: NAMING CRITERIA

Within the last few years, plans on our part to produce a field guide to the amphibians and reptiles of Mexico have congealed. As a basic step towards the completion of that goal, we were faced with developing a set of common names for these animals as such a complete list does not now exist. To this end, during January of 1979 one of us (LDW) generated and mailed to colleagues who had worked in Mexico a multi-page form upon which could be inserted suggested common names. The development and dispersal of this form constituted Phase 1 of this project. Phase 2 involves the development of a set of naming criteria to be used in developing common names for Mexican amphibians and reptiles and is represented by the present paper. Phase 3 will involve the collation of information derived from responses to the Phase 1 activity and development of a preliminary list of common names consistent with the criteria detailed below. Phase 4 will consist of the submission of selected portions of the resulting list to various specialists for final comment prior to publication of the list. Finally, Phase 5 will involve submission of the completed list of common names for Mexican amphibians and reptiles for publication.

First of all, we would like to extend our sincere gratitude to those colleagues who took the time to respond to our initial request for input on our proposed *List of Common Names for Mexican Amphibians and Reptiles*. As we expected, the comments made in response to our request were varied. But with the help of these suggestions and, as well, benefiting from the leadership provided by the SSAR Committee on Common and Scientific Names and from the criticisms of the *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* that followed in the pages of Herpetological Review (Vol. 9, No. 4 and Vol. 10, No. 1), we have tried to establish some ground rules for the standardization of methods for naming these animals. There are no unanimous opinions expressed among those responses we received as to the methods to be used nor, for that matter, the value of compiling this list. There will be, therefore, many who will disagree with one part or another of the results. This disagreement cannot be avoided. We only hope that our efforts will be of use to some and that others will understand the inherent difficulties of trying to please everyone.

Among the diversity of opinions expressed, one point was raised more often than any other (although it was not a majority viewpoint)—that of the desirability of the use of Spanish common names where appropriate. Some of the comments about our suggestion to use only English common names were: "It is their country and their animals;" and ". . . it smacks of gringoism." It should be understood that we mean no insult to Spanish-speaking people in general or Mexicans in particular. Those who know us well are cognizant that we all have had a long-term commitment to the people of Mexico and other countries in Latin America and a long-term interest in the amphibians and reptiles that occur within the boundaries of their country(ies). We originally considered using Spanish common names but dismissed the idea since our field guide will be written in English and there is adequate precedent in the Field Guide to Mexican Birds by Roger Tory Peterson and Edward L. Chalif. English common names are also used for European species in the recent Field Guide to the Reptiles and Amphibians of Britain and Europe by E. N. Arnold and J. A. Burton. For example, "Midwife Toad" is used instead of the German "Geburtshelferkrote" for *Alytes obstetricans*, and "Grass Snake" is used instead of the French "Couleuvre a Collier" for *Natrix natrix*. We feel that it would be just as inappropriate to use the Spanish common name "Escorpion" for *Heloderma horridum* as it would be to use the colloquial name "Scorpion" for *Eumeces laticeps* or "Stinging Snake" or "Hoop Snake" for *Farancia abacura*. Such usage would only promote misunderstanding. Furthermore, *Heloderma horridum* has had the name "Mexican Beaded Lizard" applied in earlier publications.

Another point frequently mentioned among the responses we received concerned the justification of the need for a list of common names. We sympathize with those who do not advocate the use of common names and do not ourselves suggest that common name usage be promoted as an alternative to using scientific names. We do feel compelled to provide, however, a list for those who feel more comfortable with such names, even though these names have no official status. Furthermore, the need is justified in order to:

1) be consistent with other field guides;
2) provide nontechnical people with names less intimidating than latinized scientific names; and
3) satisfy the requirements of listing common names on Federal Wildlife Import Declarations.

In an attempt to create a sense of order and uniformity of procedure to be used in assembling the final list, we have compiled the following GUIDELINES FOR CONSTRUCTION OF COMMON NAMES OF MEXICAN AMPHIBIANS AND REPTILES.

1) For species occurring both in the United States and Mexico, common names will be

used that appear in the "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (1978, SSAR Misc. Publ., Herp. Circular No. 7). For species excluded from the above list, the names in either Stebbins' (1966) or Conant's (1975) field guides will be used.

2) Common names proposed by authors of SSAR catalogue accounts, monographs, or other publications will be used insofar as is possible.
3) Common names developed anew will be as short and easily pronouncible as possible.
4) English common names (translated from the Spanish, where appropriate) will be used, except where the Spanish name has become part of the English language, as for example, "Axolotl."
5) Common names will use descriptive or geographic terms more often than patronyms. Ambiguous terms, such as "Peninsula," will be avoided. Instead, "Baja X" or "Yucatan Y" will be used for those species found principally on these peninsulas, where appropriate. Insular forms will be named for the island upon which they occur and, likewise, where appropriate, for the mountain range, plateau, valley, desert and so forth upon or in which they occur.
6) Hyphens and -ed endings will be avoided, except for plural descriptive terms, such as twin-spotted, cross-banded, red-eyed, blotched, spotted, speckled, and so forth.
7) Common names for genera will be that of the type species.
8) Common names for subspecies will tend to be descriptive or geographic.

The purpose of this note is to publicize the criteria we will employ in attempting to standardize common names for Mexican amphibians and reptiles. Therefore, we invite any and all comments from the herpetological community at large as we engage in this arduous task. Finally, we want to say that we are quite pleased about the enthusiasm exhibited and the support offered for this project and the field guide.

ANURA

BUFO LINDNERI Mertens. AFRICA, TANZANIA, Coast Region, Kisarawe District, on grounds of Minaki Secondary School, 23 km SW Dar es Salaam. 28 April 1976. K. M. Howell, S. Tjomlid. Specimen identified by Miss A. G. C. Grandison and deposited in British Museum (Natural History), BMNH 1978.612. Common on dirt road at edge of lowland coastal forest after heavy rain. The species was previously known only from two specimens, a male and female collected at Dar es Salaam (Loveridge, 1957, Bull. Mus. Comp. Zool. 117(2):312). An additional specimen, BMNH 1978.611 has since been collected by W. B. Rudman on the University of Dar es Salaam main campus, 20 September 1976 at the edge of secondary vegetation.

Submitted by K. M. HOWELL, Box 35064, Department of Zoology, University of Dar es Salaam, Dar es Salaam, Tanzania.

BUFO MICRANOTIS RONDOENSIS Loveridge. AFRICA, TANZANIA, Coast Region, Kisarawe District, Pugu forest, app. 23 km SW Dar es Salaam, 29 October 1977. K. M. Howell and A. M. Mutani. Specimen identified by Miss A. G. C. Grandison and deposited in the British Museum (Natural History), BMNH 1978.613. Found in moist leaf litter outside the entrance to an abandoned kaolin mine in lowland coastal forest. The species was previously known only from Nchingidi, Rondo Plateau, mainland Tanzania, 360 km south of present record, and Jangombe Swamp, Zanzibar Island, 80 km northeast of present record (Loveridge, 1957, Bull. Mus. Comp. Zool. 117(2):313).

Submitted by K. M. HOWELL, Box 35064, Department of Zoology, University of Dar es Salaam, Dar es Salaam, Tanzania.

ELEUTHERODACTYLUS COCHRANAE (Whistling *Eleutherodactylus*; Coqui Pitito) Puerto Rico, USA. Culebra Island: about 2 km NE Dewey. 17 Feb. 1979. Coll. Herpetology class (J. A. Rivero). UPR-M 5138. Several specimens heard but only one collected; in bromeliads (*Tillandsia*) high in trees in xerophytic forest. The only other native *Eleutherodactylus* known from Culebra is *E. antillensis* (one specimen known), but *Leptodactylus albilabris*, *Bufo marinus* and *E. coqui* also present, the latter two imported recently. Previously known from Saint Thomas and Puerto Rico but not from Culebra (Grant, 1931. J. Dept. Agric., P.R. 16(3):215; Rivero, 1978. The Amphibians and Reptiles of Puerto Rico. Ed. Univ., Univ. de Puerto Rico, 13).

Submitted by JUAN A. RIVERO and RAFAEL JOGLAR, Biology Department, University of Puerto Rico, Mayaguez, P. R. 00708.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: OKLAHOMA: Cimarron Co.: Black Mesa State Park. 26 May 1979. C. Stammler, J. Tollefson, H. Guarisco. Verified by W. E. Duellman. Mus. Nat. Hist., Univ. Kansas, Lawrence, KU 181594-181597. Extension of *ca.* 250 km W of previously defined distributional limits (Nelson, 1972, Cat. Amer. Amph. Rept. 122.1-122.4) in the northern portion of its range, and indicates its probable discovery in adjacent New Mexico. All four specimens were found by day beneath rocks on hillsides around a man-made state lake.

Submitted by JOSEPH T. COLLINS, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045.

TESTUDINES

CHRYSEMYS CONCINNA (River Cooter). USA. TENNESSEE: Claiborne Co.: ca. 7 km SE Tazewell (in Sycamore Embayment of Norris Lake during high water). 13 June 1975. M.A. Ewert. Univ. Utah, UU 14278. A baby. Range extension of 350 km NE into eastern Tennessee from the nearest locality record, Marion Co., TN (Iverson, 1978, Herp. Rev. 9(1):22).

Submitted by MICHAEL A. EWERT, Department of Biology, Indiana University, Bloomington, Indiana 47401.

CHRYSEMYS PICTA BELLI X ***MARGINATA*** (Painted Turtle) USA. MISSOURI: Washington Co.: 21 km SE Sullivan (Indian Creek drainage). 2 June 1976. M.A. Ewert. Carnegie Mus., CM 65580. Hatchling from oviducal egg of female uncataloged at CM. This locality is ca. 70 km W of nearest record, Randolph Co.,

IL (Smith, 1961, Illinois Natur. Hist. Survey Bull. 28(1)). Extends range into Missouri Ozarks and Meramec River Basin. On the basis of four adults and 11 hatchlings I judge that the form is most nearly *C. p. belli* with the major difference being the presence of red striping on the limbs in place of yellow or yellow and orange as in pure *belli*. The local population is quite small (5 specimens observed or collected along 4 mi of drainage system).

Submitted by MICHAEL A. EWERT, Department of Biology, Indiana University, Bloomington, Indiana 47401. ●

CHRYSEMYS SCRIPTA ELEGANS (Red-eared Slider). USA. INDIANA: Bartholomew Co.: 3 km SSW Azalia. 29 August 1975. M.A. Ewert. Carnegie Mus., CM 61494. A juvenile. INDIANA: Shelby Co.: 2 km NW Marietta. 7 June 1977. M.A. Ewert. Two photographs of a subadult female deposited at the Carnegie Museum. Extends range 75 km NNE along the East Fork White River and its main tributary, the Big Blue River (Minton, 1972, Amphibians and Reptiles of Indiana). Local populations appear small (3 oxbow systems have yielded 3-8 subadults to adults observed or collected) and are restricted to oxbow ponds.

Submitted by MICHAEL A. EWERT, Department of Biology, Indiana University, Bloomington, Indiana 47401. ●

DERMOCHELYS CORIACEA SCHLEGELI (Pacific Leatherback). USA. ALASKA: Near Cordova (Lat.60.34N., Long.145.38W.). *ca.* 1 September 1962. Specimen caught in seiner's net and killed. Verified by biologist/museum staff or Cordova Historical Society Museum. Specimen in CHSM collections. Weight: 272.4 kg., length: 175 cm. (Astrid Sandstrom, CHSM, pers. comm.). Near Craig (Lat. 55.28 N., Long. 133.03 W.). 21 August 1978. Specimen caught in seiner's net and killed. Verified by National Marine Fisheries Service personnel. Weight: 321.9 kg. (after organs removed), carapace length: 162.5 cm., carapace width: 100 cm. Temporarily deposited in regional offices of Marine Mammal Division, NMFS, Seattle, WA. with eventual deposition in the collections of Portland State University, Portland, Oregon (Mil Zahn, Marsha Schad, NMFS, pers. comm.). Additional sightings include a second Craig sighting on 21 August 1978 and a sighting near Myers Chuck (Lat. 55.44 N., Long. 132.11 W.) "recently" (Williamson, 1978, Alaska, Alaska Northwest Pub. Co., Anchorage (11):22). It is n ot known if these sightings represent turtles other than the dead Craig specimen. The Cordova specimen (Lat.60.34N.) and the recently killed Craig specimen (Lat. 55.28 N.) represent the first extant *D. c. schlegeli* specimens from the State of Alaska and the northernmost Pacific Ocean records to date (Hodge, 1976, Amphibians and Reptiles in Alaska, the Yukon and Northwest Territories, Alaska Northwest Pub. Co., Anchorage).

Submitted by ROBERT PARKER HODGE, c/o Tongass Historical Society Museum, P.O. Box 674, Ketchikan, Alaska 99901. ●

GRAPTEMYS PSEUDOGEOGRAPHICA OUACHITENSIS (Ouachita Map Turtle). USA. INDIANA: Jackson Co.: 4 km SSE Medora (oxbow, E. Fork White River). 13 May 1976 and 20 May 1977. M. A. Ewert. One of five adult females collected at this site. Same specimen mentioned in Ewert and Legler, 1978, Herpetologica 34:314-318. A hatchling from the female's eggs to be deposited at the Carnegie Museum. INDIANA: Bartholomew Co.: 2 km SSW Azalia (adjacent to main channel E. Fork White River). M. A. Ewert. Verified by R. C. Vogt. CM 65583. Establishes range in East Fork White River up to 140 km NE (st. line) from its confluence with the West Fork, where the species is known from recent records (J. O. Whitaker et al., 1977, Indiana Water Resources Research Center, Report of Investigations 8, Bloomington, IN) and other records (Minton, 1972, Amphibians and Reptiles of Indiana). The species is common up to Columbus, IN, above which the main branch of the East Fork (Driftwood & Big Blue R. reaches) changes abruptly from a sand and silt bottom to a gravel, stone and mud bottom, and *G. geographica* has been the only species of map turtle observed. INDIANA: Clark Co.: 8.7 km NE Jeffersonville, IN and 10.5 km NE the Falls of the Ohio. 7 May 1975. M. A. Ewert. Basking adult female studied at leisure from 40 m with spotting scope. Not captured. This record establishes the species in the McAlpine Pool of the Ohio River just above the Falls of the Ohio and about 140 km equidistant from the Franklin Co., IN record (above the Falls) and the Knox Co., IN record (below the Falls) (Minton, 1972, Amphibians and Reptiles of Indiana). Babcock (1977, Institute for Mining and Minerals Research IMMR 25-GR4-77, University of Kentucky) lists the species in the Ohio River up to Meade Co., KY, 80 km WSW, and below the Falls. All aforementioned new records are of *G. p. ouachitensis* c. f., Vogt (1974, Herp. Rev. 5(3):79).

Submitted by MICHAEL A. EWERT, Department of Biology, Indiana University, Bloomington, Indiana 47401. ●

TRIONYX MUTICUS MUTICUS (Midland Smooth Softshell). USA. INDIANA: Jackson Co.: 3 km SE Medora. 4 September 1975. M. A. Ewert. Carnegie Mus., CM 61502. A baby. INDIANA: Bartholomew Co.: 3 km SSW Azalia. 29 August 1975. M. A. Ewert. CM 61501, male. INDIANA: Shelby Co.: 2 km NW Marietta. 3 September 1975. M. A. Ewert. CM 61503, adult male. Establishes record of the species in the East Fork White River and its main tributary, the Big Blue River up to 150 km NE of their confluence with the West Fork White River, where the species is documented (Minton, 1972, Amphibians and Reptiles of Indiana). The species is common NE to Columbus, IN and rare at Marietta, where *T. spiniferus* is common. Adult females frequent seasonally flushed oxbow ponds and the main channel. Males are rare in oxbows, common in the main channel.

Submitted by MICHAEL A. EWERT, Department of Biology, Indiana University, Bloomington, Indiana 47401. ●

SAURIA

ANOLIS S. SAGREI (Cuban Brown Anole). USA. FLORIDA: Lee Co.: Sanibel Is., common along Periwinkle Way and Gulf Drive. 24-26 June 1977. D. Moll. Many individuals observed; several photographed, captured and released (none preserved). Locality is ca. 150 km S of Tampa-St. Petersburg populations (Oliver, Copeia 1950(1):55-56), and ca. 200 km W of populations in metropolitan Dade, Broward, and Palm Beach counties (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci. 29(2):144-154). Levy Co.: Waccasassa Marina adjacent to Waccasassa Bay State Preserve, 6.1 rd. km (by Fla. Hwy. 326) SW of Gulf Hammock. 2 June 1978. R. S. Funk. Three observed (both sexes); one adult male preserved (R. S. Funk 3673). Residents noted that only one was observed here during 1977. This site is ca. 160 km SW of Saint Augustine population (Meylan, 1977, Herp. Review 8(2):39), and 137 km N of Tampa-St. Petersburg populations (Oliver, op. cit.). This report brings to four the number of known occurrences of this species on the Florida west coast and helps document the continued spread of this introduced species in Florida in association with man.

Submitted by RICHARD S. FUNK, Department of Biological Sciences, Illinois State University, Normal, Illinois 61761, and DON MOLL, Department of Life Sciences, Southwest Missouri State University, Springfield, Missouri 65802. ●

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink). USA. OKLAHOMA: Murray Co.: Chickasaw National Recreation Area, 2.5 km SE Sulpher. 5 April 1978. OBU Environmental Biology Class. Webster Nat. Hist. Mus. 228-78. First record for the county and extends range 26 km W of nearest known locality in Johnston County. (Webb, 1970, Reptiles of Oklahoma, U. Oklahoma Press).

Submitted by JEFFREY H. BLACK and MICHAEL BUTCHER, Webster Natural History Museum and Department of Biology, Oklahoma Baptist University, Shawnee, Oklahoma 74801; E. MACDOUGALL PALMER, Rock Creek Nature Center, 5200 Glover Road, NW, Washington, D.C. 20015. ●

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). USA. FLORIDA: Brevard Co.: Floridana Beach, SR A1A. 22 April, 13 May 1978. S. Myers and W. Hutchinson. FSM/UF 43749-43751. New county record. Floridana Beach record lies 28.1 km North of Wabasso Beach record (Myers, S. 1978. SSAR Herp. Review 9(3):107). Geckos were found on a building which was formerly an exotic plant outlet. This record represents the northern most recorded locality. St. Lucie Co.: Ft. Pierce. 30 April, 17 May 1978. S. Myers and S. Phillips. FSM/UF 43752-43754. New county record. Locality lies 42.2 km south of Wabasso Beach record (Myers, S. 1978. SSAR Herp. Review 9(3):107) and 43 km north of the Hobe Sound record (Myers, S. 1978. SSAR Herp. Review 9(3):107).

Submitted by STEVEN MYERS, Department of Herpetology, Fort Worth Zoological Park, Fort Worth, Texas 76110.

SERPENTES

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet kingsnake). USA. SOUTH CAROLINA: Oconee Co.: 1.1 km E county rd. #171 (Whitewater Falls Rd.), 14.5 km N Salem, 610 m elevation. 26 June 1977. Carl Putnam. Verified by D. W. Herman, Atlanta Zoological Park, in private collection of D. W. Herman #094. First record for county and northwestern South Carolina. Nearest recorded specimens for the upper Savannah River drainage (Chattooga-Tugaloo-Savannah River systems) were reported in Rabun County and Habersham County, Georgia by Neill (1949, Herpetologica 5:8) and Herman (1977, Bull. Ga. Herp. Soc. 3(2):4-9) and Macon County, North Carolina by Williams (1978, Milwaukee Pub. Mus. Publ. 2:1-258).

Submitted by DENNIS W. HERMAN, Atlanta Zoological Park, 800 Cherokee Ave., SE, Atlanta, Ga. 30315 and CARL PUTNAM, Rt. 5 Box 37P, Anderson, S.C. 29623.

THAMNOPHIS SAURITUS SACKENI (Peninsula Ribbon Snake). USA. FLORIDA: Monroe Co., Key Largo, 11.3 km NE junc. US Hwy 1 and State Hwy 905. 3 January 1979. P. E. Moler. Fla. State Mus., UF-43827. Male. First record from upper Florida Keys. (Duellman, William E. and Albert Schwartz. 1958. Bull. Fla. State Mus. 3(5):181-324; Paulson, D. R. 1966. Quart. J. Fla. Acad. Sci. 29(4):295-308; Rossman, Douglas A. 1970. Cat. Amer. Amph. Rept., 99.1).

Submitted by PAUL E. MOLER, Wildlife Research Laboratory, Florida Game and Fresh Water Commission, 4005 S. Main Street, Gainesville, Florida 32601.

TROPIDOCLONION LINEATUM TEXANUM (Texas Lined Snake). USA. TEXAS: Duval Co., 8.0 km W, 11.2 km N Freer. 15 May 1978. G. E. Benefield. Verified by W. Seifert. Dallas Mus. of Nat. Hist., DMNH 4946. First record for county. Extends known range two counties southward and represents the southernmost locality for *Tropidoclonion* (Raun and Gehlbach, 1972, *Amphibians and Reptiles in Texas*, Dallas Mus. Nat. Hist. Bull. No. 2; W. Seifert, pers. comm.).

Submitted by GERALD E. BENEFIELD, Tulsa Zoological Park, 5701 E. 36th St. N., Tulsa, Oklahoma 74112.

VIRGINIA STRIATULA (Rough Earth Snake). USA. OKLAHOMA: Okfuskee Co.: Weleetka. 3 April 1977. David W. Lollis. Webster Nat. Hist. Mus. 189-77. First record for county on western edge of Oklahoma range (Webb, 1970, Reptiles of Oklahoma, U. Oklahoma Press).

Submitted by JEFFREY H. BLACK and DAVID W. LOLLIS, Webster Natural History Museum and Department of Biology, Oklahoma Baptist University, Shawnee, Oklahoma 74801.

RANGE EXTENSION OF THE SNAKE, *SIBON ANTHRACOPS* (COPE), IN EL SALVADOR

The range of *Sibon anthracops* (Cope) is poorly known. Peters (1960) defined it as the Pacific slopes of Costa Rica and Nicaragua and Peters and Orejas-Miranda (1970) also included Pacific Honduras. Recently, Meyer and Wilson (1971) have reported the first record for this species on the Caribbean versant of Honduras.

On the night of 2 July 1978, I collected a specimen of *Sibon anthracops* (Cope) at 575 m, 3 km E Tenancingo, Depto. Cuscatlán of central El Salvador; the snake was at 2.60 m in a tree (*Randia* sp) in an area that originally was Subtropical Moist Forest Formation (Holdridge, 1975). Presently there are only thickets, cropfields and pasture. This constitutes the first Salvadoran record, extending the known range of this species about 700 km west along the Pacific Slopes of Central America.

The specimen from El Salvador (HH 106, in my private collection) is a female and has the following characteristics: nasal divided; loreal enters orbit; no preoculars; two postoculars; temporals, 1 + 2; supralabials, 7 - 6, with the 4th and 5th entering orbit on the right side, and the 3rd and 4th entering on the left; both 6th supralabial on the right side, and 5th on the left, greatly enlarged, in contact with postoculars, primary and secondary temporals; infralabials, 7 - 6, a groove between first pair of chin shields; dorsal scale formula, 13 -13 - 13, all dorsal scales smooth; vertebral scale row not enlarged; ventrals, 170; anal plate entire; subcaudals, 74, in two rows; caudodorsal scale reduction formula:

$$\frac{6}{2+3(9)}\ \frac{2+3(8)}{4}\ 2+2(18)\ \frac{3}{V+1(45)}\ \frac{V+1(44)}{1}\ V\ \frac{1(45)}{1(46)}\ \frac{2}{(74)}$$

Total length, 482 mm; body length, 357 mm; tail length, 125 mm.

The color in life was: dorsal ground color white; 17 black bands on body, narrowed on sides, meeting on venter; 8 black bands on tail, forming rings; scale rows 2 to 7 brick red between black body and tail bands, extending laterally to ventrals, becoming most pronounced posteriorly; venter white; head black, covering laterally three-fourths of the parietals, first supralabials, upper half of those entering orbit and postoculars; first white interspace includes posterior edges of parietals, temporal region and posterior supralabials and extending to second scale behind parietals; mental, first three infralabials and anterior half of first pair of chin shields black; rest of chin white.

I have not examined type material, however, my description agrees fairly well with those given by Peters (1960), and Meyer and Wilson (1971).

The distribution of *S. anthracops* (Cope), as presently recorded, is Honduras: Coyoles, Depto. Yoro (Meyer and Wilson, 1971); El Salvador: Tenancingo, Depto. Cuscatlán; Nicasan Salvador, El Salvador, C. A. Aguacate Mountains; San Antonio de Belén; Barranca (Peters, 1960) and Tenorio, Las Cañas, Guanacaste (Taylor, 1954).

ACKNOWLEDGEMENTS

I thank my cousin Miguel O. Escobar for the field assistance and Joseph C. Mitchell for his critical reading of the manuscript. I also thank Sra. Ana Margoth Cándido de Coto for typing this manuscript.

OBSERVATIONS ON CHELONIA MYDAS MYDAS: A NORTHERLY EXTENSION OF KNOWN NESTING RANGE

Carr and Ingle (1959) documented the first nesting emergence of *Chelonia mydas mydas* on the North American Coast from hatchlings and photographs taken from Hutchinson Island, Martin County, Florida and Vero Beach, Indian River County, Florida. Additional records of *Chelonia mydas mydas* nesting activity on Hutchinson Island were reported by Routa (1967) and Gallagher *et al.* (1972). *Chelonia mydas mydas* was observed nesting on Merrit Island National Wildlife Refuge, Brevard County, Florida on July 3, 1973, approximately 5 km south of the Volusia County line, Florida (Eberhard 1975). This observation represented a northerly extension in nesting range of nearly 160 km.

On June 21, 1978, at Cape Canaveral National Seashore, Volusia County, Florida, a nesting female was observed approximately 2.5 km north of the Volusia County line. Over curvature carapace measurements were 126 cm in length and 114 cm in width. Maximum head width was 14 cm. Sixteen mm films were taken of nest construction, covering activity and beach descent. Monel and Jumbo Roto

Tags, CR1156 and FL0049, respectively, were attached to the front flippers. The same female was observed on July 14, 1978, renesting, approximately 16 km north of the Volusia County line. These observations appear to constitute the earliest and northern-most known records of *Chelonia mydas mydas* in the western hemisphere.

THE NATURAL HISTORY OF MEXICAN RATTLESNAKES

by Barry L. Armstrong and James B. Murphy

includes

* detailed observations and data on the habitat preference, daily activity, food, behavior and reproductive biology of over 50 taxa of rattlesnakes
* invaluable new information on the distribution of Mexican rattlesnakes
* forty-three figures which include forty black and white photographs (twenty-six of rattlesnakes and fourteen of specific habitats) and three maps
* an extensive bibliography on Mexican rattlesnakes

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars**, and several **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES

Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR ANNUAL MEETING NEWS

HERPETOLOGY AT THE UNIVERSITY OF TENNESSEE-KNOXVILLE

The University of Tennessee-Knoxville traces its ancestry back to 1794 when the Legislature of the Federal Territory granted a charter to Blount College two years before Tennessee achieved statehood. From the beginning, Blount College was nonsectarian and it was the first coeducational college in the United States. In 1807, the State Legislature changed the name of the institution to East Tennessee College and in 1840 it became East Tennessee University. Closed during the Civil War, the buildings of East Tennessee University served as a hospital for confederate troops and then for union soldiers. In 1869, soon after reopening, East Tennessee University was selected as a Land-Grant Institution and in 1879 became The University of Tennessee. In 1968 the Board of Trustees reorganized the institution into a State University system with the central campus at Knoxville. The present enrollment on the Knoxville campus is about 30,000, of which over 7,000 are professional or graduate students. There is a faculty of about 1300. Located on the Knoxville campus are, among others, a large College of Liberal Arts with departments of biochemistry, botany, microbiology and zoology and the Graduate Program in Ecology, the School of Architecture, and Colleges of Agriculture, Engineering, Law, Nursing and Veterinary Medicine. Close ties are maintained with Oak Ridge National Laboratory, about 20 miles west of Knoxville, through shared students and faculty. The University of Tennessee Graduate School of Biomedical Sciences is located in Oak Ridge. In addition, cooperative biological research is conducted with the National Park Service, National Forest Service and the Tennessee Valley Authority which has its headquarters in Knoxville.

The University of Tennessee-Knoxville has recently expanded opportunities for graduate studies in herpetology. Herpetological research is now being conducted under the auspices of the departments of psychology and zoology, and in the interdisciplinary Graduate Program in Ecology of the College of Liberal Arts. The latter program draws its shared faculty from various departments within the College of Liberal Arts, from the College of Agriculture, College of Engineering, Oak Ridge National Laboratory, National Park Service, and the Division of Forestry, Fisheries and Wildlife Development of the Tennessee Valley Authority. Although Tennessee occupies a critical zoogeographic position, the state is relatively poorly known herpetologically and opportunities for local behavioral, ecological and systematic studies are excellent. Field research in the immediate area is possible on the Cumberland Plateau to the west and in the Appalachian Mountains to the east. The Great Smoky Mountains National Park is but 40 miles south of Knoxville and other equally convenient natural areas include Catoosa Wildlife Management Area, Cherokee National Forest and a number of state parks and forests. The University of Tennessee maintains a state-wide network of agricultural field stations which are available for research purposes. Behavioral studies are encouraged at the newly redesigned reptile facility at the Knoxville Zoo and plans are being developed for a separately housed reptilian ethology laboratory there.

Three faculty members are directly involved in herpetological research. Dr. Gordon Burghardt (Department of Psychology and Graduate Program in Ecology) continues his long-term studies of green iguana behavior and ecology at Barro Colorado Island in Panama. This project, in collaboration with Dr. A. Stanley Rand, has involved several graduate students over the years. He is also continuing his investigations of the tongue-vomeronasal system of snakes and lizards utilizing electrophysiological techniques including EMG recording from the tongue muscles. These methods will be utilized in a comparative study of Natricine snakes. Chemical analysis of prey attack releasing substances is under way. An ontogenetic perspective underlies all aspects of Burghardt's studies.

Six graduate students are presently studying reptilian behavior under Burghardt's direction. Bryan Bock has initiated studies of caudal luring and predation in pit vipers. Marilla Davis is conducting field and laboratory studies of sociality of the eastern box turtle, *Terrapene c. carolina*. Beverly Dugan has been heavily involved in the Barro Colorado studies and her dissertation topic is social behavior of the green iguana (*Iguana iguana*). In addition, she has been studying interactions between nesting crocodiles (*Crocodylus acutus*) and nesting iguanas on Slothia Island near Barro Colorado, a pre-hatch mortality in green iguanas. Hugh Drummond's dissertation research is on amphibious predation by

AYRES HALL — The University of Tennessee, Knoxville was one of the earliest universities established on America's first frontier. It was founded in 1794, just 18 years after America declared its independence. Ayres Hall, built in 1919, has come to represent the University's mission of education for thousands of students. Photograph courtesy of the Office of Public Relations, University of Tennesse, Knoxville 37916.

garter snakes and involves a comparative field and laboratory behavioral study of predatory techniques. Drummond has three other ongoing projects: Orientation of migration by hatchling green iguanas, luring in newborn alligator snapping turtles (*Macroclemys temmincki*) (description and experimental analysis), and stimulus control of amphibious predation in northern water snakes (*Nerodia sipedon*). Roy Scudder is studying behavioral and biochemical relationships in the genus *Nerodia* using scent gland secretion lipids. Paul Weldon has a general interest in chemical communication and chemical recognition of predators and is studying chemical recognition of predatory snakes and snake skin chemistry. Dr. Doris Gove recently completed her dissertation under Burghardt's direction (The form, variation, and evolution of tongue-flicking in reptiles) and is a Visiting Assistant Professor in the Department of Psychology. Another recent Burghardt student, Dr. Harry Greene (Dissertation title: Phylogeny, convergence, and snake behavior) is presently an Assistant Professor in the Department of Zoology at the University of California at Berkeley.

Dr. Arthur C. Echternacht (Department of Zoology and Graduate Program in Ecology) joined the UTK faculty in 1975. He is continuing systematic studies of South American lizards of the genus *Ameiva* and has initiated a comparative ecological study of melanistic and non-melanistic *Ameiva* on small islands in the West Indies. He and several students are studying aspects of the ecology of *Anolis carolinensis* at the northern edge of its range at a locality near Knoxville. In collaboration with William H. Redmond, he is beginning work on a field guide to the amphibians and reptiles of Tennessee.

Six graduate students are working with Dr. Echternacht. James L. Jenkins, in a study of the energetics of optimal diet, is investigating the prey size-distance relationship as a function of hunger in adult male *Anolis carolinensis*. Robert L. Jones recently completed a Master's thesis on resource partitioning among six species of plethodontid salamanders and is drawing up a dissertation research proposal on a related subject. He has been a critical and vocal participant in discussions of local herpetological issues. William H. Redmond is performing a quantitative analysis of the zoogeography of the amphibian fauna of Tennessee and is collaborating with Raymond Stone on s study of the distributions of *Hyla versicolor* and *H. shrysoscelis* in Tennessee. Julia Wade-Smith is conducting a comparative study of reproductive strategies of female *Anolis carolinensis* from Tennessee and Louisiana. Raymond Stone is studying resource utilization and habitat selection by *Anolis carolinensis* at the study site near Knoxville. James Thompson has initiated a taxonomic study of snakes belonging to the tribe Lampropeltini.

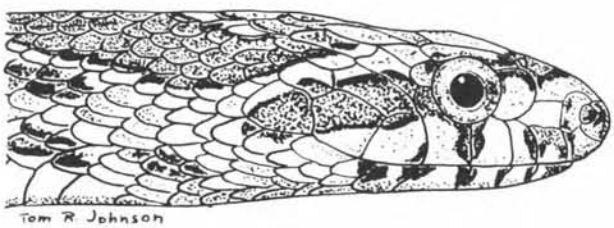
New to the faculty, Dr. Neil Greenberg (Department of Zoology and Graduate Program in Ecology) adds expertise in behavioral ecology and physiological ethology to the group. He is presently preparing an ethogram of *Anolis carolinensis* and continuing his studies of the olfactory projections in the central nervous system of *Anolis*. He is also studying forebrain control of social behavior and the neuro-endocrinology of social organization in lizards.

George A. Middendorf, working under the direction of Dr. Susan Riechert, a spider ecologist, is completing his dissertation on the energetic basis of social structure which is based on manipulative field studies of *Sceloporus jarrovi* in southeastern Arizona. He is also completing a study of thermoregulation and diel activity patterns of *Sceloporus jarrovi*, lizard responses to chemical cues of predators, and a zoogeographic analysis of the *Sceloporus torquatus* group.

An active research program is maintained by personnel of the Department of Herpetology at the Knoxville Zoological Park. Howard E. Lawler, Curator of Reptiles, is in charge of the newly renovated reptile complex. Projects in progress include studies of the natural history and reproductive dynamics of *Brachylophus fasciatus*, the influence of photoperiod variance on germ cell recrudescence in reptiles, natural history and reproduction in the tortoise genera *Pixys* and *Acinixys*, territorial scent marking by captive reptiles, nutritional value and growth potential for artificial diets in rearing juvenile boids, and the control of Ophidascaridae in a large collection of live reptiles. Collaborative research between visiting investigators and zoo staff are encouraged and plans are being made for a separately housed reptile ethology research facility on the zoo grounds. This is to be a cooperative project between the Knoxville Zoological Park at the University of Tennessee-Knoxville.

Communication within this diverse assemblage of herpetologists is fostered by a seminar series which is scheduled about twice a month to meet in the home of a faculty member. Students, faculty and outside speakers participate in an effort to keep all

UNIVERSITY OF TENNESSEE, KNOXVILLE CAMPUS



SCENIC SPOT — The area around the Humanities and Social Sciences Complex at the University of Tennessee, Knoxville, is one of the most scenic on the campus. In the center is McClung Tower, an office building for Liberal Arts faculty. At the right is the Volunteer statue, which symbolizes the spirit of the University. Photograph courtesy of the Office of Public Relations, University of Tennessee, Knoxville 37916.

informed of on-going herpetological research at UTK and elsewhere in, especially, the Knoxville area. Students (and faculty) are given the opportunity to present progress reports and give practice runs on papers to be presented at national meetings, final thesis or dissertation defenses and job interviews.

Beginning with the base of a small teaching collection in existence when Echternacht arrived at UTK in 1975, a concerted effort is being made to expand and upgrade the research collection of amphibians and reptiles maintained by the Department of Zoology. The emphasis of the collection is the southwestern United States and, especially, Tennessee. Additions have been made primarily in concert with the research projects of various graduate students and in collection of desmognathine salamanders is growing especially rapidly. We will soon have species and geographic files enabling us to communicate our holdings to interested investigators and facilitating loans. Inquiries are invited.

ARTHUR C. ECHTERNACHT, Department of Zoology, University of Tennessee, Knoxville, Tennessee 37916.

EDWARD HARRISON TAYLOR, 1889-1978

SHIFTING SANDS

The passage of Edward H. Taylor in June, 1978, has been ably noted by his successor, W. E. Duellman (1978), at the Museum of Natural History, University of Kansas, where Taylor was active for 70 years. The KU Biological Sciences Newsletter also briefly reflected upon his transit (Leonard, 1978). Biographical and autobiographical material appeared a few years earlier in a special publication of the same museum (see Taylor et al., 1975). An obituary by one of Taylor's most steadily productive students, Robert G. Webb, has also just appeared (1978). Certainly other personal appraisals can be expected to appear in the future as inevitable after-effects of the shutdown of one of the most powerful sources of intellectual energy that ever existed in herpetology.

Although much of my own views of my former mentor is embodied in notes accompanying Taylor's reminiscences (*op cit.*, 1975), some things were left then unsaid, because he was still living, that can now be expressed.

In mentally reviewing my own life in the role of perhaps the best-known of Taylor's students, sharing a great deal of field work with him in Kansas and Mexico, preparing a master's and a doctoral dissertation under his direction, working jointly with him on more projects (exclusively Mexican) than anyone else, and producing a vast interchange of correspondence, the essentials that persist are the impressions resulting from the accumulation of experiences, not the experiences themselves. It is these impressions I am moved to record. The historical details, indeed, engender so little appeal that, when not long ago Ed placed his lifetime correspondence in the archives of the University of Kansas library, I asked that my letters be removed, for I was more concerned than he that oncoming generations be spared the soon-to-be-meaningless burden of the clutter of lifetime accumulations of only once-important verbal exchanges.

At the same time it is fitting, at the behest and with the cooperation of his former wife, that alter biographical information be recorded on his progeny. That contribution forms part II of this compendium.

I

Edward Harrison Taylor was not one person; he played many roles and led several lives: the captivating raconteur, the consummate actor, the indefatigable field

man, the consort of royalty, the social lion, the slave-driver, the work-horse, the poet and writer of literature, the marathon swimmer, the bridge-expert, the under-cover sleuth, world traveller, adventurer, teacher, naturalist, incorrigible iatrophobe. In all these roles he exhibited numerous constant attributes: distrust of others, independence, inscrutability, impatience, fathomless self-confidence, adulation of and hunger for power, monumental self-sufficiency, the need to control his own life and events about him, but of complete honesty, bent only by the necessities of courtesy, varying with degree of respect engendered in him. He could be amazingly diplomatic upon significant occasions, but brutally blunt at other times. Domineering and biased, he was a factor that could not be overlooked by anyone whose life he touched. The alchemy of his and other lives was seldom neutral; almost always either sparks flew, sometimes followed by growth of intense hatred, or admiration masked all other feelings, sometimes mutual but more often one-sided, and in the latter situation usually of him, not by him. In the rare latter situations, the admiration was of the elite — of royalty, of high-level politicians, of those who wielded power. There was a certain exclusivity in his associations, a class-consciousness and keen awareness of different kinds of class, as of intellectual, social, political, etc., and of the necessity of compartmentalization of associations with those classes.

Such a many-faceted, multi-talented person can scarcely be characterized adequately, for as in the parable of the blind men and the elephant, each observer comprehends but a part of the total picture. No one ever, I think, knew him really well, and few indeed could be considered truly close friends. So far as I could observe, the closest friend of his entire life was A. Byron Leonard, who shepherded him through his final years, and especially his last few months. Byron was a friend of very long-standing, from the years when he was a student early in Taylor's tenure as a professor at the University of Kansas. But there was nothing especially close about the friendship until the last few months of his life, when no longer was it possible to live without some dependence upon others.

This is not to say that others would not lavish upon him all the affection he would accept; it was merely a matter of going so far, and no farther, in his relations with others, no matter how adulatory they might be. He loved adulation, and responded nobly to it with a widely captivating charisma, but he was nevertheless careful to avoid any extreme that would leave him "beholden" to others. There was always a curtain of aloofness close behind any appearance of warmth.

Indeed, it has seemed to this observer that Ed was sometimes a bit cruel in not acknowledging and fully appreciating the abundant concern he received from his colleagues at the University of Kansas, especially in his retirement years. He was given every comfort and convenience, watched and protected with almost fanatic care, all accepted with casual recognition but with little overt evidence of gratitude. Yet his very existence for several years was due in large part to the unflagging attention of particularly W. E. Duellman.

Of course Ed's life was not rigidly the same throughout; there was an ontogenesis of personality inevitable in anyone who successfully weaves his way among the many hazards of life to protracted old age. No one knew him well throughout that time; they knew him as a struggling, undirected undergraduate student, or as a tireless worker in his youth in the Philippines, or in his prime as a famed herpetologist at the University of Kansas, or as a retired celebrity, or as a tired, gentle old man awaiting the Final Call. He was not the same person throughout these stages of his long, active life, and to see him only as he was at any one time ignores the complexity of the total picture.

The stage least known of all, to me and to others of his professional world, is his youth prior to departure for the Philippines — the undergraduate days at the University of Kansas (where he spent his entire post-secondary school life except for periods of foreign travel), and the years that preceded them. His lengthy stay in the Philippines is sketchily known, and very little is revealed of his activities in the war years and immediately thereafter, when he participated in missions to Russia (after World War I) and in southeastern Asia (during World War II). However, the scarcity of public information on the latter two episodes was a matter of design; Ed was always extremely secretive about his role in them, content to let others guess what they may have been. Indeed, he much disliked any effort at any time to "pry" into his past or into his plans for the future, and he became abusive when rare confidences about either were shared with others. Even the most innocent revelations, when they came home to him, were likely to evoke a seemingly quite disproportionate reaction. He wanted no "press-agent," as he often sharply characterized a surprised, indiscrete confidant, although he welcomed attention to professional accomplishments. It was his personal life of which he was so extremely protective, quite to the level of paranoia at times.

The only event relative to his World War II experiences in southeast Asia that I can remember he confided in me was the occasion when his boat (size not indicated) was sunk one night in the East Indies, making it necessary for every survivor to swim a long distance (several miles?) to the nearest shore. After a while, as they were swimming, one of his shipmates called for help, exhausted, and although Ed knew he would do well just to make it on his own, he chose not to let his companion drown alone, and went to his rescue. Even though a powerful swimmer, Ed had a very long distance to go carrying an essentially dead weight. Only by the narrowest margin did he manage to make it safely to shore, there to collapse in complete exhaustion. He claimed never to have fully recovered from the strain. A few years later he, by accident, encountered the man he rescued on a train trip, but received only a grudging nod of recognition. That incident is exemplary of the sort of gratitude he often received for the help often given without acknowledgment.

Not all of the recipients of his largesse were such ingrates, however. Claude W. Hibbard, a graduate student at KU when Taylor was a professor there, was one of Ed's most outspoken admirers as long as he lived, and it was a severely depressing blow to Ed when he died.

Ed was not particularly eager to collect graduate students however. The requests almost invariably came from the other direction, and frequently various reasons came to light that led to assignment to other advisers. It seemed that never were paper credentials involved; the prospects were accepted or rejected after they arrived in person.

Taylor's professional stature has received a great deal of acclaim, and properly so. His output was prodigious and largely devoid of trivia that so deceptively embellish the publication lists of many other luminaries in his field. His taxonomic insights are legendary, even though some have proved to be illusory. Nevertheless many others have withstood the tests of time and the endless probing of his colleagues. He was anything but conventional in his interpretations.

Therefore a giant indeed he was, in professional contexts, his marks far surpassing most others, certain to endure for untold generations through the printed pages of which he produced so many (over 9000). What will be forgotten so soon is his monumental personality, so elusive of preservation yet so unequalled. I doubt that a stronger personality in the field of herpetology ever existed, partly because I have observed or am otherwise aware of quite a few of the giants of the past (and present), and partly because I cannot conceive of a more pervasive aura of authority — sometimes benevolent, sometimes fearsomely malevolent — ceaselessly emanating from anyone. It was the same sort of power, I imagine, as that possessed by the most compelling political leaders the world has ever known — a sort of hypnotic spell always at his command, in any of numerous guises adapted to the situation at hand. Very seldom was he at a loss to exert control where he wished. Impressed though I am with the magnitude of his professional stature, anyone who knew him well recognized that the professional record was just one facet of a much greater giant — of the mysterious and unique giant of innumerable facets contributing to the incomparable and incomprehensible Edward Harrison Taylor.

It should be observed that the circumstances under which Taylor's many talents flowered were not particularly favorable, and certainly some were not developed to their potential because of that. Yet the extent of their development is a documentation of the axiom that the greater the talent, the less likelihood that circumstances could prevent it from expression, although they can minimize it, and conversely, that the more marginal the talent, the greater the likelihood that unfavorable circumstances could conceal it.

The stature that Taylor achieved is not widely recognized as multidimensional,

overshadowed as it is by the documented professional eminence that is so widely, and properly, recognized. Yet multidimensional it is, of amazing breadth and depth, unlike the stature of many whose claim to fame is essentially unidimensional and a product of either exceptional scope within that framework, or of exceptional refinement and depth of penetration. It is this breadth of genius that was so outstandingly unique in Taylor.

The sadness of his passing is thus not so much that his professional work was ended, for it had run its course, and remains to awe the world for generations to come. It was that this fleshly monument, so diversely talented, so complexly beyond ordinary comprehension, should be relegated to oblivion long before it could somehow be registered in permanent record, available for scrutiny and analysis until it could be understood in detail. For a time this unique masterpiece was ours; it escaped from us without leaving with us any of its irreplaceable secrets of structure — an opportunity lost, albeit an opportunity we are even yet far too ignorant to grasp no matter how intense the desire. Nevertheless an opportunity lost, that will not come our way again, and that leaves us so helplessly diminished — and, most lamentably, so unwittingly diminished. The bells toll for us, and so many know it not. When will our rare giants leave their personalities etched in the permanent record rather than in the ephemeral and distorted memories of their contemporaries? Are they doomed forever to be buried so quickly under the shifting sands of time? We, and they, deserve something better, and we trust that knowledge to achieve that end may sometime come.

Monumental personalities are not to be expected as models throughout. There are likely to be facets that are demeaning, as well as facets of nobility; all are likely to be glaringly apparent, larger than life. Ed was no different, having a few minuses scattered among the many pluses. His famous feuds, prejudices and bluntness were not constructive, but his selective generosity, diligence and versatility were an inspiration. Students in his era were commonly trained in the arts of intolerant belittlement, of the snide pejorative, of the "search for error," much to the detriment of scientific advancement. Unfortunately at least by example he contributed to the strength of that movement through his readiness to feud. He was not a conciliator, nor was he very tolerant of shortcomings, as he saw them, in others. But he was part and parcel of his era. Fortunately that particular trend has been reversed as constructive tolerance and mutual good will and helpfulness have come to dominate both intra- and interdisciplinary interaction; it is a trend to be diligently nurtured for the health of science and the betterment of man. Judging from his actions, I think Ed came in his retirement to endorse fully the changing winds, although whether his change was merely the mellowing of old age, or a change in philosophy, or was a misinterpretation on my part, is uncertain. Certainly his negatives tended to drop out as he grew older, and his last years left him the most thoroughly likeable person of his life, insofar as I knew it.

Nevertheless he was his own master throughout, meeting the Grim Reaper alone in his own apartment, as he wished. He detested the medical profession and everything about it — hospitals, dentists, the whole gamut —except as emergency demanded or as self-
treatment could be applied. He was exceptionally resourceful in meeting his own medical needs, and in fact his only entanglement with professionals, of which I was aware, was with a dentist — an experience which only embittered him still further for he was never orally comfortable thereafter. He stoutly resisted medical consultation when he injured himself falling on ice two winters before his death, and he would have no consultants on the occasions when he would faint unpredictably in his last years.

Although his unusually strong constitution kept him in good health most of his life, he found increasing difficulty in retaining food as he grew older, and indeed starvation was the probably ultimate cause of his demise as he became too weak to leave his apartment in his last few months, although he was faithfully brought food and observed daily by nurses engaged by the Museum.

Likewise to the very end he insisted upon the same independence and privacy that marked his whole life: that no services be held after his death and that no one be notified until his ashes had been interred. Today his remains lie with a simple marker in the Pioneer Cemetery of Lawrence, Kansas: Edward Harrison Taylor, April 23, 1889—June 16, 1978.

So drift the sands of time to close over this legendary enigma with the finality of eternity — an ultimate truth no amount of discourse, review, reappraisal, eulogy or lament can alter, and before which we must bow.

II

To Hazel Clark Taylor I am indebted for a letter and its enclosures written June 26, 1978 to Irvin E. Youngberg, Secretary Emeritus of the University of Kansas Endowment Association. With her permission, excerpts from them, with a few subsequent emendations, are quoted below for the benefit of Ed's legion of personal friends and associates, and for biographical record.

"P.O. Box 66
Omena, Michigan 49674
June 26, 1978

Dear Mr. Youngberg:

Receipt of a copy of your letter to my daughter Patricia Taylor Kulick, enclosing two copies of press releases announcing the recent death of Edward H. Taylor, her father and my former husband, is greatly appreciated.

Few human beings, I believe, have lived as adults so nearly as they chose, as did Edward. Few, perhaps, have had so many loyal and devoted friends. It is evident that he chose his friends wisely.

It is my deep regret that he did not choose to seek professional medical help in his later years, in order that his life might have been prolonged. Along with his host of friends, recognition and acclaim for his contribution to science and to standards in education, he had as a stimulus an abundance of high adventure. Never could I forget the fascinating wonderful five or more years that I shared during his earlier life in the Far East!

Being a mother, I feel that an additional biological contribution that Edward made to life should be recorded, namely, his progeny. Though they did not intrude upon his special world, those issue who survive him are destined to carry into time their heritage of Edward's traits and potentialities — his concept, as I remember, of his life after death.

For such a record if it be pertinent, I enclose a resume of his issue: one daughter deceased and those surviving; one daughter, one son, four grandsons, one granddaughter and one great-grandson, born, I believe, on the day that Edward died, June 16. But the boy's father when he telephoned me the good tidings, was so bewildered that he could not quite remember whether the birth had occurred on the day of his call, or the day before!

I am exceedingly grateful to you for your courtesies and to all who helped Edward in his last days.

Sincerely,

(signed)

Hazel Clark Taylor"

Mrs. Taylor's summaries of Ed's progeny, written at the same time as the letter to Youngberg, as are follows:

A. Children

"1. Patricia Taylor Kulick, born May 28, 1923, Kansas City, Missouri. Graduated from Randolph Macon Woman's College, Lynchburg, Va. Majored in math, minored in economics. Except for mother's payment of greater part of tuition for first year she provided for herself through scholarships and summer jobs. When war was imminent she was chosen, along with 39 other women graduating from colleges east of the Mississippi, by Chaunce Vaught Aircraft Corp. to be put through Guggenheim School of Aeronautics, all expenses paid and pledged to work in Chaunce Vaught plant for one year, through all phases of production in preparation for the drawing boards and design. Before the pledged year was completed, however, she was tapped by the Navy to work on a "crash-safety" program and later to organize captured German aircraft documents. At the war's end she married, then worked for Goodyear in Akron, Ohio, on lighter-than-air craft. Then she worked for various corporations under government contract to build war planes, the orbiting platform, submarines and battleships. Her special field is *reliability*.

After 35 or more years of experience in this field, she now works for Litton's battleship program at Pascagoula, Miss. In addition to her engineering job, she has a real estate broker's license and an antique dealer's license. She restores antique and historic houses on "The Gulf" (of Mexico), does public relations for the Sierra Club, works in an engineering club and in the Episcopal church of Ocean Springs, Mississippi. She lives at 7 Windlo Circle, Ocean Springs, Miss., in a glorious old home on the shore of a bayou.

"2. Richard Clark Taylor, born March 18, 1926, Kansas City, Missouri. Veteran of World War II, having enlisted as an 18-year-old reservist, AAF. When in middle of second year at Haverford College, he was called to active duty. Through the duration of war, he never saw combat, but was shifted from one training base in USA to another. After war, he returned to Haverford on G.I. Bill of Rights. He had outside jobs, as he had had his first years, his mother paying tuition for first year and one half. He married a Bryn Mawr graduate assistant in the biology department, and majored in psychology as a pre-med, hoping to continue in medicine, but after graduation from Haverford, with so many GI's applying and already accepted in his field, there were no openings. He got a job, first in a lumber firm and, when the owner died, one in "personnel" with Swift and Co. He has developed a special type of "Industrial Relations" program for Swift, has worked for them in Mass., New Jersey, and now in Omaha, Nebraska. He has two children, one son and one daughter. He has married for a second time and has step children, two still at home, a boy and a girl. He resides at 6410 South 149 Ave., Omaha, Nebr."

B. Grandchildren

"1. Christopher Verdery, born Nov. 1946, Milford, Connecticut, to Patricia. Now lives with mother in Mississippi and assists her in restoring old houses. He is a veteran and casualty of the Vietnam war. Drafted against doctor's advice because of his very low blood sugar, was assigned to medical corps, because he did not believe in the war. Served in several army hospitals "stateside," before being sent overseas to serve with the "jungle patrols" called "nests" who were sent out at night in an attempt to capture enemy patrols. Successful for a time, Chris' nest was later ambushed. When he attempted to rescue a comrade who was badly wounded, he received many wounds, none fatal, but his right arm was broken and the radial nerve severed. Flown to hospital in States, other nerves were attached to the muscles of his arm, hand and fingers. Then he spent many months making them manipulate. Has made wonderful recovery, though still not back to normal. He has his grandfather's aversion for doctors and hospitals and his fabulous memory. His interests are the opera and trees of the USA, a subject he has studied seriously since childhood in the manner of a systematic scientist. He is a graduate of the University of California. Excellent in history. Knows Spanish, French and other European languages. Majored in philosophy in college!

"2. Philip Calvert Taylor, born March 24, 1950, South Hamilton, Mass., to Richard. Graduated Haverford College, and Medical School of Temple University, Philadelphia, Pa., with an M.D., now interning at a private hospital in Mass., expects to practice as an internist. At end of second year at Haverford, Philip took off two years in order "to see the world." Worked on canal boat from Amsterdam to many cities of Europe. Then with his sister Linda, tramped through Europe and some of the mid-East. Married last year at Temple and is father of Edward's first great-grandson. Philip and wife Janet, a graduate of Bryn Mawr, live at 479 Sherman St., Apt. 4, Canton, Mass., 02021.

"3. Linda Taylor Kettering, born Jan. 10, 1952, Hamilton, Mass., to Richard. Graduate of Drew University, in New Jersey. Majored in education, graduate years in special education for retarded and special children. Works in that field, has M.A. She spent one summer vacation with her brother Philip in Europe and in the junior year of college went to the University of Amsterdam, Netherlands, and resided with a Dutch family, under a program of Syracuse University. Her husband, Frederick Kettering, is in the auto sales business. They reside at 1333 Old Gulp Road, Villanova, Pa., but plan to move to New Hampshire.

"4. David Brian Kulick, born March 16, 1956, Akron, Ohio, to Patricia. David has finished his fourth year at Temple University, Philadelphia. Next year he hopes to receive his degree in architecture. Now is credited with A.B. in Design. Has already done professional designs for remodeling of building facades, renewal designs for urban renewal programs, and has sold numerous watercolor paintings. Has worked as a contractor, building a facade he designed for a building in the Old Town Plaza of Covington, Kentucky.

"5. William Michael Kulick, born Dec. 4, 1959, San Diego, California, to Patricia. Will be a sophomore at Haverford College this fall. Has been active in the musical activities of both high school and college. Leads a musical group "off campus." Leans toward the theatrical arts. He is a good mechanic; has wired and plumbed several of his mother's houses. For three or more years acted here in Michigan as Life Saver and Water Safety teacher for the Leelanau Township Beach. In summer of 1978 worked as Youth Director for the Omena-Traverse Yacht Club."

C. Great Grandchildren

"1. Cory Philip Taylor, born June 16, 1978, Princeton, New Jersey, to Philip out of Richard."

As a footnote to this parade of progeny, it should be observed that Ed Taylor delighted in the enrollment of his son at Haverford College, where Ed implied he had taken courses from his long-time nemesis E. R. Dunn. The association was strictly coincidental, but a strong precedent was set, since two grandchildren, one from each child, returned there for their undergraduate college degrees.

EDWARD H. TAYLOR MEMORIAL FUND

A memorial fund for graduate education in herpetology has been established at The University of Kansas Endowment Association. Persons donating $10.00 or more will receive a complimentary set of prints of four color plates. The prints of watercolor paintings by Linda Trueb recently were published in *The Biology of Equatorial Herpetofauna in Amazonian Ecuador* by William E. Duellman, and consist of 1) treefrogs, 2) poison-arrow frogs, 3) anoline lizards, and 4) false and true coral snakes. There is only a limited number available. Should you wish to contribute to the Memorial Fund, please make your check payable to **Kansas University Endowment Association** and send to E. H. Taylor Memorial Fund, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045 USA.

THE CONCEPT OF PHENOLOGY AND ITS APPLICATION TO THE STUDY OF AMPHIBIAN AND REPTILE LIFE HISTORIES

INTRODUCTION

A basic understanding in the biological sciences, especially ecology, is that organisms respond in various ways to seasonal and cyclic changes of their environment. The sequential production of leaves, flowers, fruits and seeds of many plants is familiar to us all, as is the sequence of spring emergence, mating, egg laying and hatching or birth of many animals. The study of such seasonal events and their relationship to the environment is phenology, recently defined as "the study of the timing of recurring biological events, the causes of their timing with regard to biotic and abiotic forces, and the interrelation among phases of the same or different species" (Lieth, 1974).

Modern concepts of phenology began with Carolus Linnaeus in 1751 (Hopp, 1974) and biologists, primarily botanists, have been active in this area since then. Only relatively recently have scientists in other disciplines been concerned with phenological events (Andrewartha, 1952; Cohen, 1970; Heatwole, 1976; Lofts and Murton, 1968; Perrins, 1970; Smith, 1974; and others). The meanings, uses and models have been largely developed by botanists and these are slowly being incorporated in zoological areas.

There has been a growing awareness of phenology in herpetology. Although herpetologists are aware that life history events of poikilotherms are correlated with seasonal environmental events, only recently (Dowling, 1974) has there been an effort to establish a network of observers such as the botanists have in many states and countries. In this article, I review the concept of phenology, discuss some known phenological events in herpetology, provide a rationale and methodology for a national program and suggest uses for phenological data.

THE CONCEPT OF PHENOLOGY

Phenology is concerned with the study of seasonality, "the occurrence of certain obvious biotic and abiotic events or groups of events within a definite limited period or periods of the astronomic year" (Lieth, 1974). Seasonality is obviously pronounced in temperate regions but it also occurs in the tropics (Frankie, *et al.*, 1974). Plant and animal life histories are directly or indirectly tied to recurring climatic events, such as periods of rainfall, temperature flux and photoperiod. Many organisms "key" on other, closely associated organisms, and are thus indirectly influenced by environmental forces. Most, if not all, influence of external factors is on physiological processes which, in turn, stimulate and control behavior. Indirectly influenced organisms are those whose autecology is closely tied to directly influenced habitat associates. No organism, however, is completely independent of either biotic or abiotic forces.

Species have evolved under the influence of environmental forces (abiotic) and biological interactions among species, such as competition and predation (biotic). These latter forces are the constraints that produce the limits of the realized niche, and they vary through space and time. Environmental forces, although fluctuating, recur through space and time, and thus offer factors on which an organism can cue to start or stop some life history event. Phenology, then, is concerned with the patterns of life history events and the mechanism of their direct or indirect adaptiveness to abiotic forces.

APPLICATIONS AND EXAMPLES IN HERPETOLOGY

Amphibians and reptiles offer good subjects for phenological investigations. They are poikilothermic and may be more closely tied to the physical environment than homeotherms. Some reptiles are known to detect photoperiod changes with the parietal (third) eye, and both reptiles and amphibians (herps) respond to changes in temperature and rainfall. In this regard, they are directly influenced by environmental (abiotic) factors. Herps also respond seasonally to changes in resource availability, and in this sense are indirectly influenced. Biotic factors, such as predation and competition, also bear on seasonality by placing constraints on responses.

The annual cycle in temperate reptiles, after emergence from brumation (winter dormancy), can be generalized as follows: lipid utilization for gonadal development and mating energy; mating; egg laying; hatching (or in the case of viviparous species, embryonic development and birth); appearance of young; storage of energy in fat bodies; and, winter estivation. Emergence in these animals depends, at least in part, on temperature and photoperiod. Some phenophases depend on the quality and quantity of available resources, which in turn depend on environmental factors, especially rainfall.

In amphibians, specifically anurans, the annual cycle is generalized as follows; emergence (following a short period of adequate temperature and/or rainfall); breeding; egg laying; hatching of larvae and tadpoles; metamorphosis; and storage of fat for winter estivation. As above, timing and duration of some phenophases depend on available resources.

Not all reptiles or amphibians follow these sequences. Some breed throughout the year (many salamanders), while others breed in the fall or both in spring and fall. Offspring of several turtle species overwinter in the egg or nest and emerge the following spring (Gibbons and Nelson, 1978). Many tropical species follow annual cycles related to wet and dry seasons (Licht and Gorman, 1971).

Herps have a core control system that functions in coordinating and linking environmental events. The basic components are (after Farner, 1967): 1. external environmental information; 2. perception by receptors; 3. relay to brain centers and hypothalamus; 4. evaluation by circadian clock; 5. production of hypothalamic neurohormones and transport to pituitary gland; 6. secretion by anterior pituitary of hormones involved in lipid utilization and behavior and gonadotropins that stimulate gonadal growth, production of sex hormones and gametogenesis, all leading to the attainment

of breeding condition. This basic scheme is thought to pertain to temperate reptiles, but the sequence and functioning of this system in amphibians with various life histories and species in the tropics is not yet understood.

Studies in the literature are virtually useless to an extensive phenological approach to herpetology. In Tables 1 - 4, I present dates for several phenophases from different North American localities. As indicated, the information is widely scattered in the literature and is quite imprecise. Table 1 shows that emergence times are more completely known for lizards than for snakes and turtles (Tables 2 - 4). Most of the data on snakes, including viviparous (Table 2) and oviparous (Table 3) species, deal with the phenophase of birth or egg laying. Egg laying is also the best known phenophase for turtles (Table 4). For amphibians, breeding time over geographic areas is the best known phenophase (Table 5). Emergence is equated with breeding (calling of males). Little is known of hatching dates or dates of metamorphosis in different localities.

Far too few data exist in the literature to gain even a partial understanding of the geographic variability of life history patterns of a single species. We are far behind ornithologists in collecting this kind of information; one recent study used 8544 observations to construct a phenological map of robin nesting times in the U.S. (James and Shugart, 1974). At the present time we can, at best, come up with only one or two scores of data for **any** species!

Although some data exist for some phenophases of some species, little, if any, exists for others. I can find only 12 emergence dates for the continental common garter snake (*Thamnophis sirtalis*). I can find none for termination of annual activity in this species. These dates should be made available, as I am sure many are tucked away in field notebooks. Mass collection of phenological data would aid in understanding geographic variation of life history events, the timing of these events relative to environmental forces and the understanding of the structure of amphibian and reptile communities with regard to the partitioning of time.

METHODOLOGY

It seems appropriate here to say something about data collection. Obviously, one needs to record information on phenophases and their attributes (described below). However, it is also important to collect data on biotic events and environmental factors other than herp phenophases at the same time. As Dowling (1974) points out, some species may cue a phenophase on the appearance of a phenophase of a habitat associate, for example, the production of leaves of an associated plant. Although a species' phenophase may not actually respond to an associate's phenophase, it may respond to the same environmental factor. Thus, the predictive powers of herp phenology are of obvious value. Prediction of emergence times, mating activities, *etc.*, constitutes important information for resource managers, researchers and the layman.

The methods of collecting phenophase data are simple and inexpensive. One needs a field notebook, thermometer and field guides to local reptiles and amphibians and flora. Data, in addition to herp phenophases, could include air and water temperatures (if applicable), percent cloud cover, elevation, locality, condition of selected local flora, time of day (*e.g.*, EST, CDT, *etc.*) and date. If a national program becomes established (see below), I suggest we devise data cards that can be filed and/or converted to computer tapes for eventual analysis. Regional organizations can devise data forms applicable to their own areas and coordinate efforts of individuals, societies, high school groups and college class projects. Data could be directly noted on data forms or transferred to forms from field notebooks.

DEFINITION OF HERPETOLOGICAL PHENOPHASES

In the sense used in this paper, phenology is concerned with obvious and visible life history events. The following phenophases are taken, in part, from those outlined by the US/IBP Phenology Committee (French, *et al.*, 1972) and I offer these as a basic set of phenophases on which the herpetological community should collect data. As there is great diversity in reptile and amphibian life histories, other phenophases may be suggested by workers on species that do not exactly fit these general categories.

Arrival: emergence of individuals from brumation.

Departure: observation of dormant individuals, noted absence of active individuals or observation of last active individuals.

Courtship: observation of ritual behavior or mating pairs of reptiles and salamanders.

Breeding: characteristic mating call of anuran species and/or observation of mating pairs.

Egg laying: deposition of eggs or construction of nests of oviparous species.

Larvae: appearance of larval stages of amphibians.

Metamorphosis: appearance of transformed individuals of amphibian larvae.

Hatching: observation of hatching or appearance of juvenile individuals of oviparous reptile species of frogs with direct development.

Birth: observation of parturition or appearance of juvenile individuals of viviparous species.

Table 3. Dates for selected phenophases of the oviparous colubrid snake *Elaphe guttata*.

Pennsylvania	Apr. 29-June 16	May 18-July 16	July-Sept.	Ernst, 1971
Illinois	—	May 12-July 22	—	Moll, 1973
Tennessee	May-June	July	—	Cagle, 1937
Louisiana	—	late May-July	—	Moll, 1973
New Mexico	May-July	May-July	—	Christiansen & Moll, 1973

Table 5. Breeding dates for the widely distributed tree frog *Hyla crucifer*.

LOCALITY	BREEDING PERIOD	AUTHORITY
New York	Apr. 1-June 15	Wright and Wright, 1949
New Jersey	April	Dowling, 1974
Virginia	Mar.-May	personal observation
Kansas	March	Collins, 1974
Alabama	Jan.-April	Mount, 1974
Georgia	late Nov.-March	Wright and Wright, 1949
Florida	late Dec.-March	Wright and Wright, 1949

The first observation of a given phenophase is used to score its appearance. In addition, the phenophases listed above have the following attributes:

Onset: first observation of a phenophase.

Termination: last observation of a phenophase.

Duration: time from onset to termination of a phenophase.

Extent: number of individuals in a given phenophase.

Timing: when the onset, termination and extent of a phenophase occurs during the calendar year.

CONCLUSIONS

Phenological studies of reproduction that deal with fat deposition and utilization, gonadal recrudesence, *etc.* (Licht and Gorman, 1971; Crews, 1975, for example) are important and justifiable investigations. However, phenology, in the sense used here, deals with obvious and visible events. My purpose here is to awaken the herpetological community to the importance of widespread data collection on visible herp phenophases and to make a plea for the establishment of regional and national phenology programs. Our understanding of the relation between life history events and the environment can be greatly expanded by mass collection of such data.

Dowling (1974) made a "modest" proposal to establish a phenology program in the U.S. To my knowledge, it did not provide the impetus for such a venture. He suggested that local societies and organizations make phenological studies, and implied that these organizations feed their data into a national central computer-based data set. The Virginia Herpetological Society has initiated a phenology program (Mitchell, 1976b), but to date, response has been poor. However, like any new program, it takes time to get off the ground and we expect good response in the future. No one at the national level has offered to coordinate data from societies or individuals scattered throughout the country but I concur with Dowling that this should be done.

He also suggested that we collect data on a few select species and phenophases. I disagree, as it is not too early to start collecting data on all phenophases of all species. Some data banks would be expanded rapidly, for instance, on anuran breeding phenophases, while others would expand slowly. Researchers could obtain data sets for analysis once date banks are large enough. The North American Nest Record Card Program has established user guidelines and search fees for those interested in obtaining data (D. A. McCrimmon, pers. comm.). Such guidelines could be devised for the herp phenology program. I suggest phenophase data on a national scale be collected in a manner useful for phenological mapping, a geographical approach. Phenophase maps could, by publication, be made available to the entire community. These would be useful to a large national segment: resource managers of parks, wildlife preserves, local societies, amateur naturalists, or anyone who has use (either scientific, applied or esoteric) for such information.

Opportunities in this area of herpetology for individual and group projects are immense. One can take data individually or coordinate efforts through local societies or other organizations. The high school or college biology teacher can initiate ongoing projects for classes and contribute valuable information to the national effort as well. It is important to remember, however, that data be collected in a uniform manner, no matter who collects it (see Definition section).

We are now only in the planning stage of setting up a herpetological phenology program, and my suggestions are made to be modified and improved upon. I write this article with hopes of generating interest in a national program, not to offer myself as coordinator, as it may imply.

I suggest the herpetological societies hold a roundtable discussion of invited participants at the next national meeting to consider the feasibility of setting up a national phenology program. Topics could include a rationale for establishment of such a program at this time and, if this is agreed upon, other topics can be added, such as methodology, coordination of efforts with regional societies, data format(s), appointment of a central location and society member for coordination of national data input, and last, but certainly not least, procurement of adequate and continued funding.

ACKNOWLEDGMENTS

I thank Drs. C. R. Blem, J. T. Collins, G. R. Pisani and several anonymous readers for their comments on the manuscript. Wendy R. Hoilman proofread the final draft.

ANOTHER INEXPENSIVE TURTLE TRAP

The use of hoop nets for trapping turtles has become standard procedure for the chelonian biologist since Legler's (1960) description of his own "simple and inexpensive" construction formula using aluminum tubing and cotton mesh. Rising costs of these materials has made Legler's traps relatively more expensive today than in 1960. This report is the result of my attempt to design a less expensive and more easily constructed turtle trap which still incorporated as many (or more) of the functional advantages of Legler's device as possible.

Like Legler's, my traps are based on the "funnel trap" design, but are made solely of 1" mesh poultry fencing (chicken wire). A 5' length of 5' width fencing is rolled into a 5' cylinder of approximately 18" diameter (circumference is about 56"). The overlapping seam (about 4") along the length of the cylinder is secured by bending the exposed cut wires (along the free edges) through the adjacent mesh and folding them over on the inside of the cylinder. This should be done with each exposed wire (every 1") along the entire length of both edges. The result is a secure, open-ended 5' cylinder of wire.

Four one-foot cuts are then made in each end of the cylinder and parallel to the long axis. The one-foot cuts should stop at the reinforcing wire that circles the cylinder 1' from the end. The cuts should be spaced equidistantly around the diameter of the cylinder, with the cylinder's seam positioned midway between two of the cuts. The corresponding cuts on the opposite end of the cylinder should be aligned. The open-ended cylinder is now complete along the central three feet of its length with four equal size flaps (each about 12" x 14") on each end.

To construct the throats of the funnels, each flap must be modified to form an equal trapezoid with the previously mentioned 1' reinforcing wire and the distal end of the flap comprising its parallel edges. The two flaps (one at each end) with the median seam, and the corresponding two flaps across the cylinder are then identically folded along the cut edges (those parallel to the cylinder's axis) to form the non-parallel sides of the trapezoid. The base of the trapezoid (about 14") is the reinforcing wire; the opposite parallel side is the central 6" of the distal edge of the flap. The remaining lateral right-triangular areas (with base and altitude about 4" and 12", respectively) are folded outward with respect to the cylinder, to a position perpendicular to the plane of the trapezoidal flap.

The remaining four flaps (two at each end) are folded slightly differently. They are folded in the same trapezoidal shape, but the short parallel side must measure only about 3" and the lateral right-triangular areas (about 5" x 12") must be folded completely inward (with respect to the cylinder) to lie flush against the inside of the trapezoidal flap.

The four larger trapezoidal flaps with the outward-projecting flanges are then folded down inside the cylinder at the 1' reinforcing wire diameter. The remaining four simpler trapezoidal flaps are next folded down into the cylinder. The ends of each adjacent trapezoid's short parallel side are brought into contact and wired there to produce the throat of the funnel (ca. 3" x 6"). Altering the dimensions of the short parallel side of the trapezoidal flap will alter the size of the funnel's throat, in order to accommodate the side of the turtle the collector desires or anticipates.

The completed trap is more a rectangular box (about 36" x 14" x 14") than a cylinder, and a length of nylon twine is tied through the double thickness of the seam along one of the sides, for casting and retrieving the trap.

The traps are packed by placing a trap with one rectangular side flush to the ground and compressing the trap diagonally so that a second rectangular side also comes to lie against the ground. Additional traps are similarly placed atop those already folded, and also compressed. A loop of twine is placed over each end of the stacked traps to hold them in their flattened, compressed position. Each trap is resilient enough that removal of the loops allows them to completely unfold. At most a little manual rebending or reshaping of the wire is necessary to ready the traps for setting.

Total material cost averages about $2.00 per trap (1978 prices; six-foot-width poultry fencing averages less than 40¢ a running foot). With gloves and wire cutters (or tin snips), a single trap can be constructed in about 30 minutes. I further reduce construction time by assembling several traps simultaneously step by step.

Individual traps weigh just under three pounds and (compressed) occupy a space of about 36" x 28" x 2" (or 18" x 28" x 4" if folded over). I carry traps in bundles of five or ten; ten bundled traps fit in a volume 36" x 28" x 22".

Like Ernst (1965), the bait I have found most effective and satisfactory is canned sardines (in oil). The cheapest brands can still be purchased for less than 25¢ each (or cheaper by the case). To insure speed, ease, and cleanliness of baiting and rebaiting, I prefer to punch only small holes in the can and use the entire can of sardines for each trap setting. Following use, the entire can is discarded. This procedure has the additional advantage of not permitting captured turtles to consume any bait. Thus, interference with the turtle population is kept to a minimum (important to long-term life history studies), and digestive tract contents are not contaminated (important for feeding studies). Other baiting techniques, as well as information on optimal trapping habitats are in Legler (1960). In addition to the potential trapping sites mentioned by him, I have had excellent success with funnel traps (even unbaited) placed in culvert pipes, especially if pipe diameters only slightly exceed those of the traps.

My trapping experience in Mexico and the United States with both this design and Legler's (1960) indicates that my design is at least as effective as Legler's, and further, it is my subjective opinion that the rigidity (*i.e.*, unsagging walls) of my traps facilitates more rapid entrance of turtles. I have frequently caught as many as ten to fifteen *Kinosternon* in one trap in a single one-hour setting.

In conclusion, I feel that in addition to being less expensive, my trap design has two distinct advantages over Legler's (1960). The first is greater durability coupled with pliability, reflecting the construction materials. Alligators, muskrats, large snapping turtles, and other animals have literally turned the funnels of my traps inside out to gain their freedom. At most, repairs to the traps involved minor bending and wiring, whereas cotton nets similarly damaged are not so easily repaired. In addition, even treated cotton netting is not as long-lived as steel wire (nylon netting is an obvious alternative, but the cost is considerably higher). Several of my traps have endured major annual field trips to Texas and Mexico, and regular local use in Florida and Indiana for over five years, and show little sign of age. I have almost eliminated rust problems by not leaving traps in the water when not in use and by storing them in a dry place between use.

A second advantage of the wire trap is its non-absorbency. Cotton (or even nylon) hoop nets such as Legler's (1960) often dry very slowly, whereas simply shaking a wire trap removes nearly all excess moisture. This reduces the amount of dirt and debris that clings to the traps and eliminates the problem of placing dripping traps in the field vehicle. In addition, unpleasant, fishy odors from bait or habitat sampled are often absorbed by hoop nets, but are not a problem with wire traps.

ACKNOWLEDGMENTS

Diderot Gicca, Peter Meylan, and Ron Magill were indispensable in field testing the traps and offering suggestions for improvement. They each have made more trap settings for me than I'm sure they care to admit. My traps were designed and implemented while I was supported by the University of Florida and housed at the Florida State Museum.

SHELL DEFORMITY IN A BOX TURTLE

The Malayan box turtle, *Cuora amboinensis* (Daudin) is distributed throughout the S. E. Asian region (Pritchard, 1967; Smith, 1931).

From a consignment of such turtles given to the Sentosa Corallarium in Singapore in May 1978, a female adult specimen (carapace length 17 cm) with a deformed shell was recovered. It is now kept alive at the Zoology Department of the University of Singapore.

A normal specimen is shown in figure 1. The specimen with the deformed shell is shown, partially extended, in figure 2. The deformity is apparent in the disproportionate growth of the marginals and plastron in relation to the carapace. The carapace does not appear to be kyphotic as its normal shape is retained. Figure 3 shows clearly the overgrown plastron (length 19 cm) extending beyond the anterior and posterior margins of the carapace whereas in the normal shell, the plastron never protrudes beyond the carapacial margin.

The turtle when fully extended appears to be too big for its carapace. Its movements are not affected by the deformed shell. However, when retracted, the plastron cannot be pulled up to provide complete protection to the animal as is the case for the normal individuals. The hinge between the pectorals and the abdominals of the plastron is immobile because of bone thickening and does not allow the anterior and posterior halves of the plastron to be pulled up to conceal the soft parts.

I wish to thank Mr. E. L. Lim, Curator of the Sentosa Corallarium for giving me the specimen.

LICKING BY NEONATAL LIZARDS IN RESPONSE TO NOVEL STIMULI

Individuals in the anguid genera *Gerrhonotus* and *Ophisaurus* typically lick new objects in terraria (F. R. Gehlbach, A. F. Echelle, pers. comm.). This behavior also occurs in the iguanid lizard, *Sceloporus jarrovi* (De Fazio *et al.*, Copeia 1976:706-709). Because no experimental tests of substrate licking have been published for any neonatal or anguid lizards, I decided to test the behavioral significance of substrate licking in neonatal *G. coeruleus*.

Six, three month-old (6-8 cm TL), individually marked specimens were housed in two, adjacent 25 x 25 cm terraria, three per unit (randomly assigned). The lizards were born in captivity 29-30 September 1977 to a female from Humboldt County, California, and immediately separated from her. Limestone rocks, a water dish, and soil were in each terrarium. Each lizard was hand-fed two mealworms every two days following that day's experimental observations. Novel objects used in the tests were a 5 x 10 cm piece of oak bark and 3 x 5 x 7 cm limestone rock, presumably bearing lizard's odors, moved from the adjacent terrarium.

The subjects were given a two-week conditioning period. Then, the two terraria (lizard groups, A, B) were alternately considered experimental (four days with novel object) and control (four days without object) during tests with the bark followed by the rock. Number of substrate licks/lizard was counted at 1600-1800 hrs. each day. Each terrarium was watched for alternating 15 min. periods, with the order reversed each day of a test period. Illumination was a 40 watt bulb 25 cm above each terrarium floor (22-27°C).

Substrate licking was most frequent when new objects were present in the terraria but declined in frequency during the experiments (Table 1), perhaps because of habituation to the succession of stimuli (X^2=32, $P<0.001$, in a test for heterogeneity of the bark vs. rock results). Although group A lizards licked more often than group B lizards (X^2=42, $P<0.001$; X^2=9, $P<0.05$, in the bark and rock tests, respectively), the behavior of both groups supports De Fazio *et al.* (1976) in that licking is elicited by novel stimuli.

While individuals of two, different lizard families (Anguidae, Iguanidae) exhibit licking behavior, its general function (olfactory exploration and orientation) is apparently the same in both. Moreover, the present tests suggest that licking becomes less frequent with repeated stimulation and may be innate, since the neonates had very limited contact with their mother. Learning among certain of these subjects cannot be discounted, but at least one individual may have licked innately if learning took place.

Table 1. Substrate licking by neonatal *Gerrhonotus coeruleus* in response to novel stimuli.

Data are number of licks/group of three lizards/eight-day test period (*$P<0.001$).

GROUPS	BARK			ROCK

News Notes

SIGMA XI GRANT OMITTED

The following grant from the Society of Sigma XI was inadvertently omitted from the list published in **Herpetological Review** 10(1): 7, March 1979:

Scott M. Moody, Museum of Zoology, University of Michigan, Ann Arbor. Consequences of continental drift on the evolutionary history of the lizard family Agamidae. $150.

GECKO INFO SOUGHT

Private collector and breeder of geckos is interested in contacting other breeders and collectors of geckos for exchange of information and dispersal of captive bred progeny. Nine species are presently available as surplus (both sexes), and individuals are also desired for breeding. Enough interest may warrant production of a newsletter. Those interested should contact: Dr. Michael J. Miller, Gekkonidae Breeding Foundation, 5223 South Francisco, Chicago, Illinois 60632, USA.

INFORMATION REQUESTED ON HUNDRED PACE VIPER

Roger Conant, Director Emeritus of the Philadelphia Zoological Garden, is devoting his time largely to research in herpetology and currently is endeavoring to complete a long monograph on the genus *Agkistrodon*, in collaboration with the late Howard K. Gloyd. There are several statements in the literature to the effect that the Hundred pace viper, *Agkistrodon acutus*, of southeastern Asia, reproduces by laying eggs as opposed to being a live-bearer; but no information about specific instances is available. If anyone associated with a live reptile collection has any hard data on the subject, please write to Roger Conant, Adjunct Professor, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131.

THE ELUSIVE CENTROLENID TADPOLE

Many of us have raised centrolenid tadpoles from eggs, but few have actually seen, or collected, these tadpoles in the field. If you have (or if you have raised froglets starting with freshly-collected eggs), please write to: JAIME VILLA, Biology, University of Missouri, Kansas City, Mo. USA 64110. Any information, no matter how fragmentary, will be greatly appreciated.

State Reptile

NORTH CAROLINA

On Friday, March 16, 1979 the North Carolina Senate approved a House-passed bill making the Eastern Box Turtle (*Terrapene c. carolina*) the official state reptile. The Eastern Box Turtle thus joins the ranks of the cardinal, the honeybee, the dogwood, the pine, gray squirrel, the Scotch Bonnet (state shell), the channel bass and the emerald to be honored by the state's law makers. The sponsor of the bill, Representative Chris Barker, stated that "In order for the turtle to make progress, he must stick his neck out" and "I think state officials and the General Assembly should emulate this."

CANNIBALISM INFORMATION REQUESTED

A literature search on cannibalism in reptiles is nearly completed, and the resulting information will be compiled into a review paper. I would appreciate any unpublished observations of reptile cannibalism in captivity or in the field so the review will be as complete as possible. Please contact Joseph C. Mitchell, Department of Biology, Virginia Commonwealth University, Richmond, Virginia 23284.

NOTICE OF A PERMANENT FROZEN TISSUE COLLECTION

The Museum of Vertebrate Zoology announces the establishment of a frozen tissue collection. During the past five years samples of tissues and blood have been taken from a variety of amphibians, reptiles and mammals. Emphasis is on exact data concerning geographic origin and identification, and voucher specimens are deposited in the regular collections of the Museum. The collection now contains samples from 3300 amphibians (45 genera) and reptiles (110 genera) and 5000 mammals (97 genera). Most specimens are represented by a sample of plasma, hemolysate and various organs including liver, kidney and muscle. Samples have been frozen in the field at -76°C or -196°C, and subsequently held in the laboratory at -76°C.

We encourage the donation of scientifically important samples of frozen tissues for inclusion in this collection. These frozen materials are available to qualified investigators subject to certain restrictions. All inquiries about loans and donations should be addressed to the Director, Museum of Vertebrate Zoology, 2593 Life Sciences Building, University of California, Berkeley, CA 94720 USA.

NEW PUBLICATIONS AVAILABLE

First Supplement to a Check List of West Indian Amphibians and Reptiles, by Albert Schwartz, Richard Thomas, and Lewis D. Ober, Carnegie Museum of Natural History Special Publication (5): 35 pp. $2.00.

SPECIAL OFFER: Supplement (above) and *A Check List of West Indian Amphibians and Reptiles* (1975), regular $6.25 value - **both** for $4.00.

Order from: Publications Secretary, Carnegie Museum of Natural History, 4400 Forbes Ave., Pittsburgh, PA 15213.

WORCESTER STATE COLLEGE RECEIVES FEDERAL GRANT TO STUDY RARE TURTLE

The U.S. Fish and Wildlife Service (OES) has awarded a research contract to Worcester State College biologist, Terry E. Graham, for his proposed study of the rare Plymouth red-bellied turtle. Graham's research will be directed towards filling the considerable gaps in our understanding of this reptile. According to Graham, "knowledge of the feeding habits, nesting behavior, reproductive biology, survival, and distribution of these animals in Plymouth County, Massachusetts is largely unknown and may have considerable bearing on future deliberations regarding critical habitat designation and the continued survival of this endangered turtle. Through the use of radio-telemetry, x-ray techniques, live trapping, and intense field observation, I hope to learn all that I can about the red-belly before the end of this year."

The Plymouth red-bellied turtle is known from only a small group of ponds in Plymouth. Within recent years the land around some of these ponds has undergone extensive housing development and turtles have been found shot at one location. Earlier this year a significant step towards conserving these animals was made when the Nature Conservancy acquired a 181 acre tract of land including Crooked Pond, a known refuge of the red-belly.

Graham, whose expertise on the red-belly goes back more than ten years, indicates that unless we do all that we can to help these creatures, they may become extinct in the not too distant future. He is, however, optimistic that with effective protection and sound management this unique Massachusetts resource can be saved.

WORLD CONFERENCE ON SEA TURTLE CONSERVATION

The World Conference on Sea Turtle Conservation is being held under the joint auspices of the following U.S. government

agencies and private organizations which comprise the Conference Steering Committee:

World Wildlife Fund - U.S.
Defenders of Wildlife
New York Zoological Society
National Marine Fisheries Service
U.S. Fish & Wildlife Service
U.S. Department of State
Center for Environmental Education

Russell E. Train, President of World Wildlife Fund - U.S., is Chairman of the Steering Committee.

The Conference will assemble for the first time an international forum of scientists, conservationists and government officials for catalytic efforts directed at finding solutions to sea turtle conservation problems, as well as focusing public attention on an urgent species and resource conservation problem.

The Conference will be held at the Conference Center in the U.S. State Department, Washington, D.C., November 26-30, 1979.

PROPOSED SESSION TOPICS INCLUDE:

Value and importance of sea turtles
Present knowledge of sea turtle biology
Major threats to survival
Review of the status of world populations of sea turtles
Review of existing protective legislation and management
Conservation strategy: recovery plans, treaties, etc.

CONFERENCE SCIENTIFIC COMMITTEE

George Balazs - Hawaii Institute of Marine Biology
Mona Bjorklund - United Nations Environment Program
Archie Carr - University of Florida
Ken Dodd - U.S. Fish & Wildlife Service
David Ehrenfeld - Rutgers University
Wayne King - New York Zoological Society
Tom Lovejoy - World Wildlife Fund - U.S.
Peter Pritchard - Florida Audubon
James Tyler - National Marine Fisheries Service

Address All Correspondence to Vivian Silverstein, 1244 19th Street NW, Washington, D.C. 20036 202-659-9510

THIRD ANNUAL SSAR REGIONAL HERPETOLOGICAL SOCIETIES CONFERENCE
12 AUGUST 1979

University of Tennesse, Knoxville, Tennessee

Conference Co-moderators:
Tom R. Johnson and John Murphy

1:00 PM Introductory remarks. **Tom R. Johnson** (SSAR)

1:10 PM Legislation: How It Effects You and How You Can Affect It. **Hugh Quinn** (SSAR and Houston Zoological Gardens)

1:40 PM Tennesse's Wildlife Regulations Pertaining to Amphibians and Reptiles. **James M. Smith** (Tennessee Wildlife Resources Agency)

2:00 PM Establishing a State Rare and Endangered Species List for Pennsylvania Amphibians and Reptiles, and Regulations to Protect Them. **C. J. McCoy** (Carnegie Museum)

2:25 PM Regulations and Permit Requirements Concerning Federally Listed Rare and Endangered Amphibians and Reptiles. **C. Kenneth Dodd, Jr.** (U. S. Fish and Wildlife Service, Office of Endangered Species)

2:50 PM Federal Regulations Pertaining to Zoo Operations. **James P. Bacon, Jr.** (San Diego Zoo)

3:25 PM American Alligator Management in Louisiana and Federal Regulations. **Ted Joanen** (Louisiana Department of Wildlife and Fisheries)

3:50 PM State and Federal Regulations Concerning the Sale of Herptiles. **Louis Porras** (The Shed — Miami, Florida)

4:25 PM Florida's Wildlife Regulations and the Pet Trade. **Paul E. Moler** (Florida Game and Fresh Water Fish Division)

4:45 PM Current Status of California's Herp Regulation. **John Brode** (California Dept. Fish and Game)

5:30 PM DINNER (site to be announced at conference)

6:30 PM Open meeting of assembled RHS representatives — discussion of general interest and resolutions. **John Murphy** (SSAR and Chicago Herpetological Society)

7:30 PM COLOR SLIDE PRESENTATION. All attending the RHS Conference are encouraged to bring their best herptile slides (limit 15).

NOTE TO ALL CONFERENCE PARTICIPANTS: Registration for the conference will begin at noon (no charge). Tables will be available for regional herp society representatives to display/sell their publications and other materials. No live specimens permitted.

HERPETOLOGICAL SKELETONS SKULLS

Prepared for educational and display needs.

Over 1000 specimens in stock. From 2 in. tree frog to 7 ft. monitor lizard and 16 ft. python.

We welcome your requests and inquiries.

Geographic Distribution

CAUDATA

AMBYSTOMA LATERALE (Blue-Spotted Salamander). USA: CONNECTICUT: Fairfield Co: Danbury, Center Pond Brook. 2 October 1978. S. Fuller. Verified by J. D. Lazell, Jr. Museum of Comparative Zoology no. 96573. Extends range in Connecticut *ca.* 80 km SW; second locality for state (Klemens and Dubes, 1978. Herp. Review 9(2): 61).

Submitted by JAMES D. LAZELL, Jr., Massachusetts Audubon Society, Lincoln, Massachusetts 01773. ●

AMBYSTOMA TREMBLAYI (Tremblay's Salamander). USA: WISCONSIN: Sheboygan Co: Kettle Moraine State Forest, T14N, R20E, Sec. 20, E½. April 1977. J. Riedi and R. A. Sajdak. Alive in RAS personal collection. Mean erythrocyte area =1058 m². Kettle Moraine State Forest, T13N, R20E, on road between Sec. 6 & 7. 31 March 1978. J. A. Buday. Milwaukee Pub. Mus. Herpetol. Collection, MPM #16311. Mean erythrocyte area = 1027 m². Fond Du Lac Co: Kettle Moraine State Forest, T13N, R19E, Sec. 24, N½. 5 April 1978. J. A. Buday and R. A. Sajdak. MPM #16325. Mean erythrocyte area = 1011 m². Verified by A. A. Williams. These specimens extend the known range *ca.* 250 km SSE of previous Wisconsin records (Briggs, 1974, Herp. Rev. 5(1):18-19) and *ca.* 265 km NW of Indiana records (Minton, 1972, Amphibians and Reptiles of Indiana).

Submitted by RICHARD A. SAJDAK and JOSEPH A. BUDAY, Zoology Dept., University of Wisconsin-Milwaukee, Milwaukee, WI 53201. ●

STEREOCHILUS MARGINATUS (Many-lined salamander). USA: FLORIDA: Columbia Co: Osceola National Forest: intersection of FR 234 and Deep Creek (SW¼ NE¼ Sec. 32, T 2S, R 18E). 25 June 1977. S. P. Christman. Verified by H. W. Campbell. Florida State Museum, UF 39968. Southwestern extension of range of 29 km, first record for Columbia County, and first definite record for the Suwannee River (Gulf of Mexico) drainage (Christman and Kochman, 1975, Florida Sci. 38(3):139-141).

Submitted by STEVEN P. CHRISTMAN, HOWARD W. CAMPBELL, CHARLES R. SMITH, and HOWARD I. KOCHMAN, National Fish and Wildlife Laboratory, U.S. Fish and Wildlife Service, 412 N.E. 16th Ave., Gainesville, Florida 32601. ●

SALIENTIA

ELEUTHERODACTYLUS PLANIROSTRIS PLANIROSTRIS (Greenhouse frog). USA: LOUISIANA: in 8 hectare area surrounding Odenheimer Aquarium in Audubon Park Zoo, New Orleans. 31 August 1976. R. Atkinson & D. Dugas. Identified by B. Shreve & K. Forsgaard, Museum of Comparative Zoology. MCZ #92621-27. First record for Louisiana and a range extension of over 500 km (Conant, *A Field Guide to Reptiles and Amphibians of Eastern and Central North America*, Houghton Mifflin Co: Boston). The mottled phase of this frog has been observed in this locality since Spring 1975. The striped phase has not been seen.

Submitted by MARK PLOTKIN, Department of Herpetology, Museum of Comparative Zoology, Harvard University and RICH ATKINSON, Audubon Park Zoo, New Orleans. ●

RANA VIRGATIPES (Carpenter frog). USA: FLORIDA: Columbia Co: Osceola National Forest, numerous localities over northern half of forest. 9-30 March 1977. S. P. Christman, C. R. Smith, D. Gicca. Most specimens released; vouchers in Florida State Museum (UF 39383-5, 40226). First records from Columbia County and extends the known range about 35 km to the SW of the previous known limits (Means and Christman, 1976. *in* J. N. Layne, ed. Inventory Rare Endangered Biota of Florida. Fla. Audubon Soc., Microfilm). The southernmost locality is a cypress dome near the jct. of FS 234 and FS 263 (SE¼ Sec. 28, T2S, R18E) and the westernmost a similar dome at NW½ Sec. 13, T2S, R17E. The species is not especially abundant but appears widely distributed in cypress domes and the fetterbush phases of bay swamps throughout the northern half of the National Forest.

Submitted by STEVEN P. CHRISTMAN, HOWARD W. CAMPBELL, CHARLES R. SMITH, and HOWARD I. KOCHMAN, National Fish and Wildlife Laboratory, U.S. Fish and Wildlife Service, 412 N.E. 16th Ave., Gainesville, Florida 32601. ●

TESTUDINES

EMYS ORBICULARIS (European Pond Tortoise). SPAIN. MENORCA: BALEARIC ISLANDS: At Cala Enporter (south coast of island), in an irrigation ditch approx. 1 km inland. June 15, 1978. Collected and identified by C. Mattison and J. Pickett. An adult and a juvenile, the former observed only, the latter maintained alive by author. Confirms presence of this species on Menorca. Listed, but localities not given, by Salvador (1974, Guia de los Anfibios y Reptiles Espanoles, I.C.O.N.A., Madrid), but absent according to Arnold and Burton (1978, A Field Guide to the Reptiles and Amphibians of Europe, Collins, London). This small area of irrigated fruit groves probably represents the only suitable habitat for this species on the eastern half of Menorca.

Submitted by C. MATTISON, Department of Zoology, University of Sheffield, England. ●

CLEMMYS INSCULPTA (Wood Turtle). USA: MICHIGAN: Lapeer Co: Metamora-Hadley Recreation Area, 5 km NW Hadley. 30 May 1978. G. W. Schuett. Verified by R. E. Gatten, Jr. Private collection of GWS, 22313-1. First record for the county and extends range approximately 65.3 km NE of previous eastern record from Livingston Co. (pers. comm., R. Conant; C. H. Ernst; M. Hensley). Collected in a field near the entrance of the park. Subsequent collecting did not produce further specimens although one nearby resident when shown the present specimen said he had seen similar turtles from the area in the past.

Submitted by GORDON W. SCHUETT, 5061 Sheila Dr., Toledo, Ohio 43613. ●

GRAPTEMYS GEOGRAPHICA (Map Turtle). USA: MISSOURI: Dallas Co: 8.8 km SW Eldridge, Niangua River; Laclede Co: 4.8 km SW Nebo, Gasconade River. J. Ward. 17 Jun 78. Joseph P. Ward Collection, JPW 985, 986 and living. Records of this species in Missouri are limited. These specimens verify occurrence within range depicted in Anderson (1965) and Conant (1975); see *P. concinna* reference previously unsubstantiated.

Submitted by JOSEPH P. WARD, 808 MMKM Drive, Bellevue, NE 68005. ●

PSEUDEMYS (CHRYSEMYS) CONCINNA HIEROGLYPHICA (River Cooter). USA: MISSOURI: Laclede Co: Gasconade River, 4.8 km SW Nebo. 17 June 78. J. Ward. Joseph P. Ward Collection, JPW 994 and living specmen. Extends range 177 km NW nearest record, and approx. 55 km N range as depicted in Conant (1975) and Anderson (1965, *The Reptiles of Missouri.* Univ. Missouri Press, Columbia). One adult male sighted and two hatchlings collected. Two males collected by J. Ward, Sept. 1969, in North Fork White River, 3 km NE Tecumseh, Ozark Co, Mo., (specimens lost on loan) further substantiate occurrence of this species in mid-Missouri.

Submitted by JOSEPH P. WARD, 808 MMKM Drive, Bellevue, NE 68005. ●

SAURIA

AGAMA AGILIS. ASIA: IRAN: Jawad-Abad/Abardesh (railway station), 110 km SE Tehran. 17 June 1978. H. -H. Schleich. Zoological State Collection, ZSM 291/1978. Extends range 90 km SE of old record, 35 km SSW Tehran (Schleich. 1977. Herp. Rev. 8(4):126-129). This species ranges from Pakistan, Afghanistan, USSR to Iraq (Leviton and Anderson. 1970. Proc. Calif. Acad. Sci. 38(10):163-206). Specimen was collected under small *Acacia.*

Submitted by H. -H. SCHLEICH, Dept. of Herpetology, Zoological State Collection (ZSM), Munich, West Germany (BRD). ●

AGAMA CAUCASICA (Caucasian Agama). ASIA: IRAN: TEHRAN: Siah sang (10 km N Rudehen). 30 May 1978. H. -H. Schleich. Zoological State Collection, ZSM 289/1978/1-3. Range extension of 4 km W old record, 100 km E Tehran in Valley Golezard (Schleich. 1977. Herp. Rev. 8(4):126-129). Valley Golezard, 4 km W Polurd, NE Tehran. 5 June 1978. H. -H. Schleich. ZSM 290/1978. Elevation 2500m. An extension of range 35 km NW of old record cited above. This species ranges from Turkey to USSR, Iran and Afghanistan to Pakistan (Leviton and Anderson. 1970. Proc. Calif. Acad. Sci. 38(10):163-206).

Submitted by H. -H. SCHLEICH, Dept. of Herpetology, Zoological State Collection, Munich, West Germany (BRD). ●

SERPENTES

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake). USA: MISSOURI: Camden County, Lake of the Ozarks State Park. April 25, 1978. D. R. Ewing and L. C. Watkins. Verified by R. Goellner, Curator of Reptiles, St. Louis Zoological Park. First record for county and confirms presence of species in the north central Missouri Ozarks (Anderson, 1965. *The Reptiles of Missouri.* Univ. Mo. Press., Columbia). Specimen was photographed and released. Color slides of specimen are on file in the Natural History Section, Missouri Department of Conservation.

Submitted by TOM R. JOHNSON, Missouri Department of Conservation, P.O. Box 180, Jefferson City, Missouri 65102 and LARRY C. WATKINS, Florence Jones Reineman Wildlife Sanctuary, R. D. 1, Dolgeville, New York 13329. ●

COLUBER CONSTRICTOR (Racer). USA: NEW MEXICO: Mora Co., 27.4 km N Las Vegas. 10 June 1978. M. E. Seidel. Verified by L. D. Wilson. Univ. New Mexico, UNM 34629. First record for county; fills in gap in poorly known portion of the range (Wilson, 1978. Cat. Amer. Amph. Rept.: 218.1-218.4). Scale and tooth counts are typical of *C. c. flaviventris.* Collected in ecotone between pinyon-juniper and ponderosa pine forest at *ca.* 1829-1981 m.

Submitted by M. E. SEIDEL, Department of Biological Sciences, Marshall University, Huntington, West Virginia 25701 and LARRY DAVID WILSON, Division of Intercurricular Studies, Miami-Dade Community College, South Campus, Miami, Florida 33176. ●

CROTALUS ADAMANTEUS (Eastern Diamondback Rattlesnake). USA: ALABAMA: Mobile County; Dauphin Island, on the north side of the island 10 km from the east end. 26 August 1978. W. Schroeder. Verified by K. Marion. Museum of Comparative Zoology, Harvard University. MCZ-156188. Length 117 cm. First recorded for Dauphin Island (Jackson and Jackson, 1970, Quart. J. Florida Acad. Sci. 33(4): 181-287). Two other specimens were sighted on 26 August, 1978. On 28 August, 1978 a second specimen (126 cm) was killed in the same area. Habitat "atypical" for *C. adamanteus,* sandy beach to high salt marsh covered by typical gulf coast vegetation.

Submitted by WILLIAM W. SCHROEDER, University of Alabama - Marine Science Program, Dauphin Island Sea Lab, P.O. Box 386, Dauphin Island, AL 36528. ●

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). USA: MASSACHUSETTS: Franklin Co: Sunderland, 1.6 km N Sunderland Center, W slope, Mt. Toby. 12 June 1978. J. Coddington. Verified by James D. Lazell, Jr. Museum of Comparative Zoology no. 154766. Extends range *ca.* 22 km N to new northern limit in Connecticut Valley and state (Babcock, 1929. **The Snakes of New England,** Boston Soc. Nat. Hist., p. 17). Additional living examples encountered and photographed; strong evidence of northward range expansion in historically well-known area.

Submitted by JAMES D. LAZELL, Jr., Massachusetts Audubon Society, Lincoln, Massachusetts 01773. ●

ERIDIPHAS SLEVINI. MEXICO. BAJA CALIFORNIA DEL SUR: Gulf of California, Isla Danzante. 28 July - 2 August 1974. S. Strand. California Acad. Sci. No. 140097. New island record (Soule and Sloan, 1966, Trans. San Diego Soc. Nat. Hist. 14:137-157). The specimen is unusually heavily pigmented in contrast to other insular and peninsular specimens, although the ventral surface of the body of all known specimens is immaculate. BAJA CALIFORNIA DEL NORTE: 7 km W (by road) Bahia de los Angeles. 7 Sept. 1978. R. L. Seib. California Acad. Sci. No. 146982. First state record. Extends range 200 km NNW Sand Ignacio, Baja California Sur, Mexico (Seib, In press, *Herp. Review*), and 480 km NNW type locality, Puerto Escondido, Baja California Sur, Mexico. Collected at 21:00 by lantern light in a dry, rocky wash. The snake was actively crawling on a large granite boulder where several leaf-toed geckos were taken. In captivity, this specimen of *Eridiphas* ingested these geckos, *Phyllodactylus xanti,* on two occasions, each time regurgitating the lizard within a few hours. In contrast, the same specimen of *Eridiphas* successfully feeds upon *Uta stansburiana* and *Hyla regilla.*

Submitted by ROBERT L. SEIB, Museum of Vertebrate Zoology, University of California, Berkeley 94720. ●

NATRIX NATRIX PERSA. ASIA: IRAN: Aẑarbaijn: 10 km W Maku. 20 May 1978. H. -H. Schleich. Zoological State Collection, ZSM 292/1978. Range extension of 400 km W of oldest westernmost record near Astara on western shore of Caspian Sea (Schleich. 1977. Herp. Rev. 8(4):126-129). Ranges from Iran westward to Yugoslavia and the southern Balkan (Mertens. 1960. Die Amphibien and Reptilien Europas).

Submitted by H. -H. SCHLEICH. Dept. of Herpetology, Zoological State Collection, Munich, West Germany (BRD). ●

NERODIA RHOMBIFERA (Diamondback Water Snake). USA: TEXAS: Starr Co: 1 km N Garciasville, pools in Arroyo Garcia at US Hwy 83. 9 Oct 1976. J. Ideker. Verified by J. Ideker. MN HC/JI 4374. ♂, 577 mm TL, 530 mm SV, tail broken. Specimen fills hiatus along the Rio Grande between natural range (Webb Co, Texas: Brown, 1950, *An Annotated Check List of the Reptiles and Amphibians of Texas,* Baylor Univ. Stud., 259 pp.) and introduced range (Cameron Co, Texas: Conant, 1977, J. Herp. 11(2):217-220).

Submitted by JOE IDEKER, McDonnel Natural History Center, P.O. Box 1433, Edinburg, Texas 78539. ●

RHADINAEA FLAVILATA (Pine Woods Snake). USA: GEORGIA: Camden Co: Little Cumberland Island. 22 Aug. 1978 T. M. Mann. Verified by J. E. Kraemer. Specimen was photographed and released as the size of the population was unknown. Diagnostic photo sets will be given to the Univ. of Ga. and to the Savannah Science Museum. Habitat: Pine needle carpeted forest floor; sandy soil with little organic matter. Nearby vegetation included *Serenoa repens, Quercus virginiana, Pinus elliottii, Vaccinium arboretum, Myrica cerifera, Juniperus* sp., *Ilex* sp., *Persea* sp., and *Vitis* sp. There is a man-made artesian-fed sulphur water pond 30m SW of the collection site. First sighting of this species on a barrier island other than Shackleford Banks, N.C. (Gibbons and Coker, 1978, Amer. Midl. Natur.

Submitted by TOM MANN, P.O. Box 8453, Clemson, South Carolina 29632 and JED E. KRAEMER, Dept. of Zoology, Univ. of Ga. 30602. ●

SONORA MICHOACANENSIS MUTABIL-IS. (Mexican Ground Snake). MEXICO: Sinaloa; Plomosus, 1066 m. 25 August 1976. J. A. Campbell. Verified by D. R. Frost. University of Texas at Arlington, UTA R-7227. First record for the state of Sinaloa and a range extension of *ca.* 150 km NW from the nearest locality, Jesus Maria, Nayarit. This species may occur in adequate habitat (montane tropical deciduous forest) as far north as southeastern Sonora and southwestern Chihuahua.

Submitted by DARREL R. FROST, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

THAMNOPHIS SIRTALIS CONCINNUS X PICKERINGI. (Common Garter Snake). USA: WASHINGTON: Snohomish County: Jennings Memorial Park, Marysville. 15 July 1977, 26 September 1977, 1 May 1978. G. C. Norman and B. R. Norman. Verified by S. B. Ruth, Tuskegee Institute, Alabama. Museum of Vertebrate Zoology, Berkeley, number unknown, and B. R. Norman personal collection, 008 and 017. Based on visual characteristics, the two specimens collected in 1977 are approximately 80% *T. s.*

concinnus and 20% *T. s. pickeringi* (S. B. Ruth, personal communication), and were collected in an area naturally uninhabited by *T. s. concinnus*. The third specimen, collected in 1978, seems to exhibit characteristics nearer to *T. s. pickeringi* and lacks the substantial red-orange on the dorsal head that is present in the 1977 specimens. These may be accidental intergrades due to human introduction of *T. s. concinnus* since the nearest locality for this subspecies is calculated to be in Lewis Co., WA (Stebbins, 1966, A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston).

Submitted by B. R. NORMAN, 820 West Fourth Avenue, Olympia, Washington 98502. ●

TYPHLOPS VERMICULARIS (Vermiform Blind Snake) ASIA: IRAN: Tehran: Siah sang (10 km N Rudehen). 30 May 1978. H. -H. Schleich. Zoological State Collection, ZSM 293/1978. Range extension of 50 km E old record at Tehran (Schleich. 1977. Herp. Rev. 8(4):126-129). Ranges from Yugoslavia to Albania, Bulgaria, Greece, Turkey, Syria, Israel, Egypt, USSR, Afghanistan and Iran (Leviton and Anderson. 1970. Proc. Calif. Acad. Sci. 38(10):163-206).

Submitted by H. -H. SCHLEICH, Dept. of Herpetology, Zoological State Collection, Munich, West Germany (BRD). ●

ADDITIONAL RECORDS OF SALAMANDERS OF THE *Ambystoma jeffersonianum* COMPLEX FROM ONTARIO, CANADA

All four species of the *Ambystoma jeffersonianum* complex (Uzzell 1964) are known to occur in Ontario (Weller and Sprules 1976; Weller, Sprules, and Lamarre 1978; Weller and Menzel, *in press*). Recent collecting has demonstrated that *A. jeffersonianum*, *A. platineum*, and *A. tremblayi* are more widely and continuously distributed than had previously been known. Species of this complex cannot be clearly distinguished on the basis of morphology alone. The ploidy, therefore, was determined by erythrocyte nucleus size (Weller, Sprules, and Lamarre 1978), and by counting chromosomes (karyotyping).

This paper reports these new localities, and the geographic significance of these records. The order of localities corresponds to the north south progression of solid circles in Figure 1. NMC refers to National Museum of Natural Sciences, Ottawa, Ontario; and, ROM, to Royal Ontario Museum, Toronto, Ontario.

AMBYSTOMA JEFFERSONIANUM (Jefferson salamander). York Co, 6.4 km NE Nobleton (43° 57'N 79° 36'W). 27 April 1978. J. Lovisek and G. Davis. ROM 10304; 1 specimen. Verified by W. F. Weller from erythrocyte nucleus size and morphology: Peel Co, 4.6 km E Belfountain (43° 47'N 79° 57'W). 21 April 1978. D. Servage. Identified by collector by obtaining diploid larvae from a large cluster of eggs: Regional Municipality of Hamilton-Wentworth, 4 km W Dundas (43° 14'N 79° 59'W). 5 April 1978. B. Mackenzie. One specimen (male), returned to pond. Verified by W. F. Weller from erythrocyte nucleus size and morphology. These records extend the known range by 44 km to the north (Figure 1).

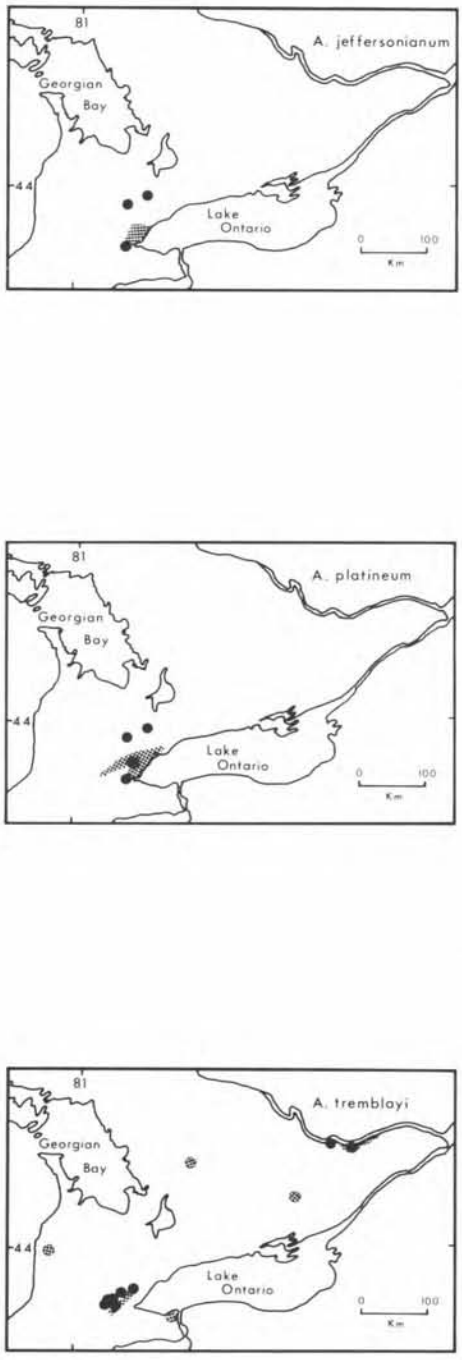

Figure 1. Distribution of *Ambystoma jeffersonianum*, *A. platineum*, and *A. tremblayi* in Ontario, Canada. Stippled areas denote the previously known range; solid circles represent localities reported in this paper.

AMBYSTOMA PLATINEUM (Silvery salamander). York Co, 6.4 km NE Nobleton (43° 57'N 79° 36'W). 27 April 1978. J. Lovisek and G. Davis. ROM 10305; 1 specimen. Verified by W. F. Weller from erythrocyte nucleus size and morphology. Peel Co, 4.6 km E Belfountain (43° 47'N 79° 57'W). 23 April 1978. D. Servage. DS 0038, 0073-75; 4 specimens. Verified by collector from karyotype and morphology. Halton Co, 1.2 km S and 3.2 km E Campbellville (43° 29'N 79° 57'W). 11 April 1978. D. Servage. DS 0020; 1 specimen. Verified by collector from karyotype and morphology. Regional Municipality of Hamilton-Wentworth, 4 km W Ancaster (43° 14'N 79° 59'W). 7 and 11 April 1978. B. Mackenzie. Six specimens, returned to pond. Verified by W. F. Weller from erythrocyte nucleus size and morphology. These records extend the known range northward by 44 km (Figure 1).

AMBYSTOMA TREMBLAYI (Tremblay's salamander). Regional Municipality of Ottawa-Carleton, Fitzroy Harbour (45° 28'N 76° 13'W). 21 and 22 August 1978. W. F. Weller and T. N. Tobias. NMC 18333; 18 specimens. Verified by W. F. Weller from erythrocyte nucleus size and morphology. Regional Municipality of Ottawa-Carleton, Britannia Filtration Plant, city of Ottawa (45° 22'N 75° 48'W). 29 April 1978. S. Darbyshire. DS 0079-89; 11 specimens. Verified by D. Servage from karyotype and morphology. Halton Co, 1.2 km S and 3.2 km E Campbellville (43° 29'N 79° 57'W). 11 April 1978. D. Servage. DS 0021; 1 specimen. Verified by collector from karyotype and morphology. Wellington Co, 1.7 km W Aberfoyle (43° 28'N 80° 10'W). 6 April 1978. D. Servage. DS 0030; 1 specimen. Verified by collector from karyotype and morphology. Waterloo Co, Cambridge (43° 22'N 80° 20'W). 19 April 1977. G. R. Francis and C. A. Campbell. Two specimens, unavailable for examination. Verified by W. F. Weller from erythrocyte nucleus size and morphology. Waterloo Co, Cambridge, Beake Pond (43° 19'N 80° 21'W). 4 May 1977. T. N. Tobias. Three specimens, unavailable for examination. Verified by W. F. Weller from erythrocyte nucleus size and morphology. Waterloo Co, Branchton (43° 18'N 80° 17'W). 1 May 1977. C. A. Campbell. One specimen, unavailable for examination. Verified by W. F. Weller from erythrocyte nucleus size and morphology. Waterloo Co, 0.9 km N and 1.7 km E Ayr (43° 19'N 80° 26'W). 21 April 1978. D. Servage. DS 0035, 0036, 0039-45; 9 specimens. Verified by collector from karyotype and morphology. These records indicate that this species is more widespread in the areas of western Lake Ontario and eastern Ontario (Figure 1).

Specimens in the private collection of D. Servage (DS) are destined for the herpetological collection of the Royal Ontario Museum. We thank Ontario Hydro for

permission to publish their record of *A. tremblayi* from Fitzroy Harbour.

Rhadinaea montecristi MERTENS: AN ADDITION TO THE SNAKE FAUNA OF HONDURAS

A recent collecting trip to Honduras produced a single specimen of *Rhadinaea montecristi* Mertens, 1952, which represents a new record for that country. It is otherwise known from a series of specimens from the type locality, Hacienda Monte Cristo, 2200 meters elevations, mountains of Metapán, Depto. Santa Ana, El Salvador (Myers, 1974).

The Honduran specimen (LSUMZ 36594) was collected on 14 April 1978 and came from a locality locally known as El Portillo de Ocotepeque, 20.1 km E Nueva Ocotepeque, Depto. Ocotepeque, at a point where the Carretera Occidente crests the Sierra de Merendón. The specimen came from beneath a log in a pasture on a hill above the road at an elevation of 2010 meters. This spot was illustrated by Meyer (1969). The original vegetation of the area was closed canopy cloud forest (Lower Montane Moist Forest formation of Holdridge, 1967), now existing in restricted patches on the more inaccessible areas at this locality. The Honduran locality for *R. montecristi* is approximately 31 km E of the type locality in El Salvador.

The specimen is a male exhibiting the following characteristics: ventrals, 157; anal plate divided; subcaudals, 84; dorsal scale rows 19-19-19; supralabials 8-8 (4th and 5th entering orbit); infralabials 8-8 (4 in contact with anterior chin shields, 5th the largest); loreal 1-1; preocular 1-1; postoculars 2-2; temporals 1+2; total length, 401 mm; tail length, 125 mm; relative tail length, 0.312. The color pattern of the Honduran specimen is in agreement with the composite description given by Myers (1974) for the specimens from El Salvador. The color pattern in life was as follows: dorsum rust brown to row 4; a weakly differentiated blackish vertebral line on the middorsal scale row; black dorsolateral stripe on the lower one-third of row 4, all of row 3 (except for the dorsal apex, upon which there is a white spot), and the upper two-thirds of row 2; black lateral stripe on lateral edges of ventrals and lower one-third of row 1; area between dorsolateral and lateral stripes cream; dorsum of head rust brown; supralabials and eye stripe pale yellow, borders of those areas black; chin pale yellow grading to golden yellow on the throat and remainder of venter.

Herpetofaunal associates of *Rhadinaea montecristi* at this cloud forest locality include: *Bolitoglossa dunni, Bufo coccifer, Hyla salvadorensis, Plectrohyla guatemalensis, Ptychohyla spinipollex, Barisia moreleti, Anolis sminthus, Sceloporus malachiticus, Leptophis modestus, Ninia attrata, Rhadinaea godmani, R. kinkelini, Thamnophis cyrtopsis, Bothrops bicolor, B. godmani* (Meyer and Wilson, 1971, 1973; Wilson, McCranie, and Porras, 1978, *in press*; Wilson and Meyer, *in press*). Of particular interest in this list are the two other species of *Rhadinaea, godmani* and *kinkelini*. Occurrence of three species of *Rhadinaea* in syntopy is limited, although several examples of two-species syntopy are known (Myers, 1974). *Rhadinaea godmani, R. kinkelini,* and *R. montecristi* are already known to occur syntopically at Hacienda Monte Cristo on Cerro Monte Cristo in El Salvador (Myers, 1974). These three species are all members of the *godmani* group. Other examples of three species syntopy include: (1) *R. hesperia, R. omiltemana,* and *R. taeniata* at Chilpancingo, Guerrero, México; (2) *R. decorata, R. gaigeae,* and *R. marcellae* in the Xilitla region, San Luis Potosí, México; (3)*R. decipiens, R. decorata,* and *R. guentheri* at La Lola, Prov. Limón, Costa Rica; (4) *R. calligaster, R. decipiens,* and *R. pulveriventris* on Cerro Pando, Prov. Bocas del Toro, Panamá. In only the second example are the three species members of the same species group (the *decorata* group). At El Portillo de Ocotepeque, *R. kinkelini* was first collected in 1968, *R. godmani* in 1976, and *R. montecristi* in 1978. It is unlikely that any additional species of *Rhadinaea* will be collected at this locality.

Herpetological Husbandry

NOTES ON THE REPRODUCTION OF THE MUSSURANA, *Clelia clelia* (Daudin)

Neotropical ophidian reproduction is poorly documented and fragmentary. Fitch (1970) includes nothing on *Clelia clelia*, a relatively common and widespread form. On 1 March 1972 an emaciated *Clelia clelia*, of unknown origin, was received at Max Allen's Zoological Gardens, Eldon, Missouri, and maintained in isolation from other snakes. On 14 January 1975 she initiated egg laying, depositing two eggs. Another egg was deposited 15 January, however, complications developed and the snake died 17 January. Dissection revealed nine additional, undeposited eggs. Unfortunately the eggs were accidentally exposed to non-optimal temperatures during incubation and any potential development was precluded. The specimen measured 199.0 cm. after preservation.

SECOND-GENERATION CAPTIVE RHINOCEROS IGUANA HATCHED

In October 1975, the new Parque Zoologico Nacional successfully hatched 7 Rhinoceros iguana, (*Cyclura cornuta cornuta*), the first time they have had captive reproduction in the zoo of this species.

In June 1978, two females of this group nested, laying within a day of each other, 12 and 15 eggs respectively. The eggs were removed from the exhibition area and placed in an incubator at 31°C. The first iguanas began to break their shells on 7 September, and all hatched between the 8th and the 15th of the month. The incubation period was from 81 to 87 days for both clutches. Out of 144 *Cyclura* eggs laid this year, 115 are of *C. c. cornuta* and 29 are of Ricord's iguana (*C. ricordi*).

At the time of writing, 55 Rhinoceros and 11 Ricord's iguana are successfully hatched. A remaining 27 are still incubating, of which a majority are expected to hatch. Thirty-nine eggs have been lost due to fungus infections, and 12 proved to be infertile. At present, all hatchlings are doing well.

Both species live sympatrically in xerofitic (sic) areas of the Dominican Republic and are threatened by competition with hervivorus (sic) livestock, predation by introduced animals and capture for human consumption and commercial trade locally.

SUCCESSFUL CAPTIVE REPRODUCTION OF YELLOW ANACONDAS

On 23 September 1978, six young Yellow anacondas were discovered in the large constrictor display at the Ellen Trout Zoo, where the adults have been housed since their arrival at the zoo two years ago. Also in the exhibit were six infertile eggs and one individual born dead. Breeding was not observed, so the gestation period is not known. The adults had been observed in "serpentine entanglement" in the fall of 1976; however, no young resulted from this mating.

. . . from AAZPA Newsletter, 19(12): 12. 1978.

CUBAN CROCODILES HATCH

On 9 June, a nest was constructed by the female Cuban crocodile with alfalfa hay provided for that purpose and 19 eggs were laid at the California Alligator Farm. These eggs were set up in various mediums; some left in the nest, some in Vermiculite in a styrofoam container in the snake house, some in damp paper in a crock in the snake house and some in Vermiculite placed in a dead air type poultry incubator, held at 87°. The latter proved successful after 86 days, and three Cuban crocodiles were hatched on Labor Day.

The hatchlings are doing well accepting crickets, pink mice, cut beef and cut liver.

Book Reviews

A HERPETOLOGICAL COOKBOOK: HOW TO COOK AMPHIBIANS AND REPTILES. By Ernest A. Liner. 60p. Privately printed May 20, 1978. Available from Ernest A. Liner, 310 Malibou Blvd., Houma, Louisiana, 70360. Price $5.50.

At last there exists a publication for those herpetologists who live, sleep, and EAT their work. The "jet set" now has nothing on the herpetologist who can serve dried iguana eggs instead of caviar at his next party (for those herpetologists who can afford to serve caviar in the first place).

At first reading I thought of this as one of those "cute" publications (such as *Herpervertological Review*), but, on closer examination, I found that there are some sound recipes contained within. While some did not (and still do not) sound like something very likely to come in contact with my buccal cavity, some appear to be very good. Being a barbeque fan, the barbequed rattlesnake (or any snake of acceptable size) appealed immediately, as did several of the turtle preparations. At the opposite end of the spectrum, the deep-fried Brandied *Amphiuma* will probably never be served in my house. (Liner's recipe calls for three tablespoons of cognac; three liters may be a more realistic amount.)

This publication contains 228 recipes, although 39 of these are preparations not directly dealing with amphibians and reptiles, and include sauces or gravies that enhance many of the recipes.

A few typographical errors were found (*i.e., the contents of the Turtle Goulash, page 53, are duplicated*), but these are minimal and do not detract from the overall work.

For those readers who like to try something different, for those herpetologists who have always wondered what to do with the many DOR *Terrapene* that dot our highways (be sure to use only the freshest!!), or for those herpetogourmets who will try anything, this is the book for you. My only complaint was the lack of caecilian or tuatara recipes.

JAMES L. KNIGHT, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

Legislative Alert

USFWS PROTECTED AMPHIBIANS AND REPTILES: AN UPDATE

The following is a list of the 81 amphibians and reptiles considered endangered (E) or threatened (T) by the United States Fish and Wildlife Service as of 30 September 1978. This list is derived from a similar one prepared by the USFWS and published in the Federal Register (1978, Vol. 43, no. 238), but has been reorganized and condensed for ease of use. Some taxa listed below are protected in geographic areas that comprise only a part of their total known range. Refer to the official USFWS list for this information.

AMPHIBIANS:

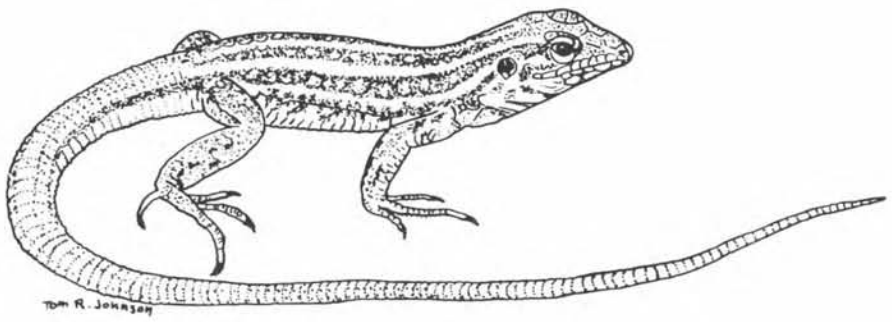
- Chinese Giant Salamander *Andrias d. davidianus* (E)
- Japanese Giant Salamander *Andrias davidianus japonicus* (E)
- Santa Cruz Long-toed Salamander *Ambystoma macrodactylum croceum* (E)
- Desert Slender Salamander *Batrachoseps aridus* (E)
- Red Hills Salamander *Phaeognathus hubrichti* (T)
- Texas Blind Salamander *Typhlomolge rathbuni* (E)

- Stephen Island Frog *Leiopelma hamiltoni* (E)
- Israel Painted Frog *Discoglossus nigriventer* (E)
- Golden Coqui *Eleutherodactylus jasperi* (T)
- Panamanian Golden Frog *Atelopus varius zeteki* (E)
- Houston Toad *Bufo houstonensis* (E)
- Monte Verde Toad *Bufo periglenes* (E)
- Cameroon Toad *Bufo superciliaris* (E)
- African Viviparous Toad *Nectophrynoides* sp. (E)
- Pine Barrens Treefrog *Hyla andersoni* (E)

REPTILES:

- Loggerhead *Caretta caretta* (T)
- Green Turtle *Chelonia mydas* (E/T)
- Leatherback *Dermochelys coriacea* (E)
- Hawksbill *Eretmochelys imbricata* (E)
- Atlantic Ridley *Lepidochelys kempi* (E)
- Pacific Ridley *Lepidochelys olivacea* (T)
- Galapagos Tortoise *Geochelone elephantopus* (E)
- Geometric Turtle *Geochelone geometrica* (E)
- Madagascar Radiated Tortoise *Geochelone radiata* (E)
- Angulated Tortoise *Geochelone yniphora* (E)
- Shortneck Tortoise *Pseudemydura umbrina* (E)
- South American Turtle *Podocnemis expansa* (E)
- South American Turtle *Podocnemis unifilis* (E)
- River Terrapin *Batagur baska* (E)
- Spotted Pond Turtle *Geoclemmys hamiltoni* (E)
- Asian Three-keeled Turtle *Geoemyda tricarinata* (E)
- Indian Sawback Turtle *Kachuga tecta tecta* (E)
- Burmese Peacock Turtle *Morenia ocellata* (E)
- Aquatic Box Turtle *Terrapene coahuila* (E)
- Indian Flapshell Tortoise *Lissemys p. punctata* (E)
- Cuatro Cienegas Softshell *Trionyx ater* (E)
- Indian Softshell *Trionyx gangeticus* (E)
- Peacock Softshell *Trionyx hurum* (E)
- Black Softshell *Trionyx nigricans* (E)

- American Alligator *Alligator mississippiensis* (E/T)
- Chinese Alligator *Alligator sinensis* (E)
- Apaporis River Caiman *Caiman crocodilus apaporiensis* (E)
- Broadsnout Caiman *Caiman latirostris* (E)
- Yacare *Caiman yacare* (E)
- American Crocodile *Crocodylus acutus* (E)
- African Slendersnout Crocodile *Crocodylus cataphractus* (E)
- Orinoco Crocodile *Crocodylus intermedius* (E)
- Morelet's Crocodile *Crocodylus moreleti* (E)
- Nile Crocodile *Crocodylus niloticus* (E)
- Philippine Crocodile *Crocodylus novaeguineae mindorensis* (E)
- Ceylon Mugger Crocodile *Crocodylus palustris kimbula* (E)
- Mugger Crocodile *Crocodylus p. palustris* (E)
- Cuban Crocodile *Crocodylus rhombifer* (E)
- Siamese Crocodile *Crocodylus siamensis* (E)
- Gavial *Gavialus gangeticus* (E)
- Black Caiman *Melanosuchus niger* (E)
- Congo Dwarf Crocodile *Osteolaemus tetraspis osborni* (E)
- African Dwarf Crocodile *Osteolaemus t. tetraspis* (E)
- Tomistoma *Tomistoma schlegeli* (E)



- Tuatara *Sphenodon punctatus* (E)

- Round Island Day Gecko *Phelsuma guentheri* (E)
- Day Gecko *Phelsuma newtoni* (E)
- St. Croix Ground Lizard *Ameiva polops* (E)
- Giant Anole *Anolis roosevelti* (E)
- Barrington Land Iguana *Conolophus pallidus* (E)
- Bluntnose Leopard Lizard *Crotaphytus silus* (E)
- Anegada Ground Iguana *Cyclura pinguis* (E)
- Mona Ground Iguana *Cyclura stejnegeri* (T)
- Island Night Lizard *Klauberina riversiana* (T)
- Bengal Monitor *Varanus bengalensis* (E)
- Yellow Monitor *Varanus flavescens* (E)
- Desert Monitor *Varanus griseus*
- Komodo Island Monitor *Varanus komodoensis* (E)

- Puerto Rican Boa *Epicrates inornatus* (E)
- Mona Boa *Epicrates m. monensis* (T)
- Jamaican Boa Epicrates subflavus (E)
- Indian Python *Python m. molurus* (E)
- Eastern Indigo Snake *Drymarchon corais couperi* (T)
- Atlantic Salt Marsh Snake *Nerodia fasciata taeniata* (T)
- San Francisco Garter Snake *Thamnophis sirtalis tetrataenia* (E)
- New Mexico Ridgenose Rattlesnake *Crotalus willardi obscurus* (T)

SSAR members are advised that the above list represents only those amphibians and reptiles currently having an official USFWS status. Many additional herpetological taxa are controlled under other governmental agreements and conventions.

JOSEPH T. COLLINS and JAMES L. KNIGHT, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

Richard D. Worthington, Current Literature, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

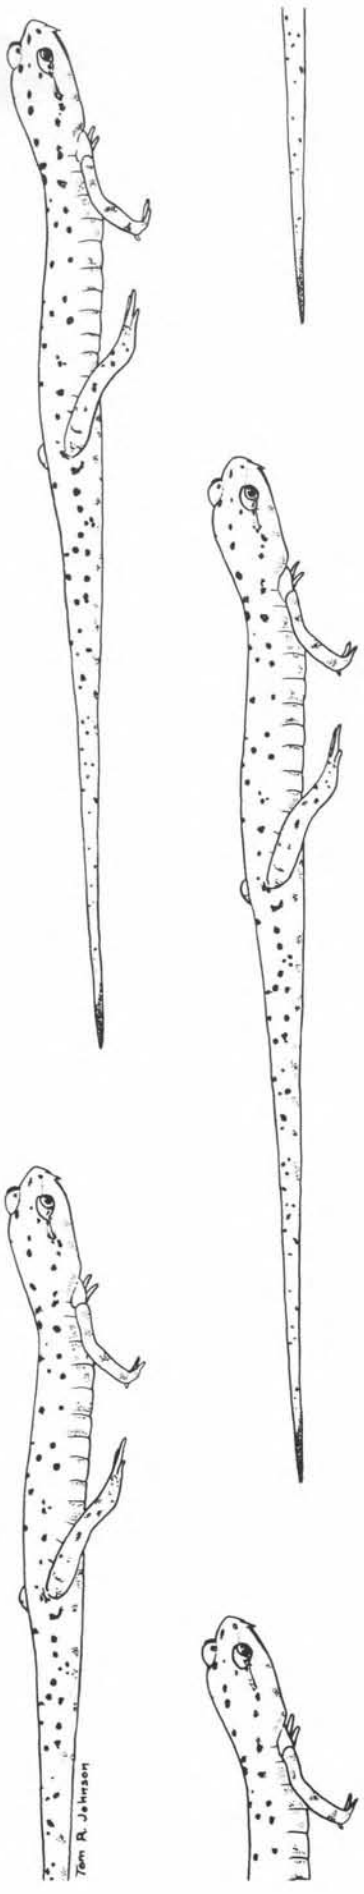
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member . . .	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR Annual Meeting News

SSAR ANNUAL MEETING NEWS

The 22nd annual meeting of the Society for the Study of Amphibians and Reptiles will be held in conjunction with the 27th annual meeting of the Herpetologist's League at the University of Tennessee, Knoxville, Tennessee, from 12 to 16 August 1979.

PROGRAM SUMMARY:

Sunday, 12 August	Registration, SSAR Board of Directors Meeting, HL Board Meeting, Third Annual Regional Herp Society Conference (SSAR), Liaison Committee Meeting
Monday, 13 August	Contributed Papers, Iguanine Lizard Behavior and Ecology Symposium (SSAR), Social
Tuesday, 14 August	Contributed Papers, Iguanine Lizard Behavior and Ecology Symposium (SSAR), Captive Reptile and Amphibian Management Symposium (SSAR), Picnic, SSAR General Business Meeting
Wednesday, 15 August	Contributed Papers, Desmognathine Salamander Systematics Workshop (HL), HL Business Meeting
Thursday, 16 August	Contributed Papers, Salamander Mimicry Symposium (HL)

SPECIAL ACTIVITIES:

Herpetological Art Show and Crafts Show and Sale. Depending on interest: Spouse and family trips to Biltmore Mansion (Asheville, North Carolina); Gatlinburg, Tennessee; University of Tennessee Arboretum and the Museum of Atomic Energy, Oak Ridge, Tennessee. Daytime child care may be available if demand warrants it.

GENERAL INFORMATION:

Pre-registration forms, including call for papers and other information, will be mailed to members of the two societies in February. Copies of the meeting information will be sent on request to interested persons.

Housing in air-conditioned dormitories will be available.

Transportation: Individuals planning to travel by air should make reservations into McGee-Tyson Airport in Knoxville.

LOCAL COMMITTEE CHAIRPERSON:

Arthur C. Echternacht
Department of Zoology and Graduate Program in Ecology
Walters Life Science Building
University of Tennessee
Knoxville, Tennessee 37916
Phone: (615) 974-6041

SSAR Business

SSAR Contributors

Once again it is my pleasure to acknowledge those members who made financial contributions to the Society for fiscal 1978. Although some donations were only a dollar or so, others were substantial, but what is most important is that so many members were willing to contribute and the $1195 so obtained formed a healthy part of our total income.

Observations of Ant Predation Upon Brooding Salamanders

The role of brooding behavior as an antipredator device has been discussed for three plethodontid salamanders: Plethodon cinereus (Bachmann, 1964), Aneides aeneus (Snyder, 1971), and Desmognathus ochrophaeus (Forester, 1974). In the latter study, females were subjected to multiple encounters with known or suspected vertebrate and invertebrate predators. Attending females were uniformly aggressive to all predator classes, although there was a significant inverse correlation between successful clutch defense and predator size.

The purpose of this note is to present a striking exception to the above correlation and to document predation by the red ant Lasius subumbratus upon Desmognathus ochrophaeus females and their eggs.

During the summer of 1973, I was conducting a field study pertaining to the adaptiveness of parental care in the mountain dusky salamdner, D. ochrophaeus. The study site was along a slow-moving mountain stream near the town of Highlands, North Carolina.

In late June, shortly after the onset of oviposition, I located 30 attending females and independently confined each with its eggs in a 9 cm plastic petri dish (Fig. 1-A). The lid of each dish contained four 3 mm ventilation holes. Each dish containing a confined female and her clutch was placed under a piece of moss at the exact location of her natural nesting cavity.

The eggs of each clutch were counted at six day intervals to determine the weekly mortality rate of attended eggs in the absence of predation. At the onset of the experiment (June 21, 1973), the $\bar{x}$ number of eggs/clutch was 18.39. On August 8 (the eighth check), the $\bar{x}$ number of eggs/clutch had decreased to 15.81. Hatchlings were beginning to emerge from many of the clutches. On August 14, I returned for the ninth check. Twenty-seven of the 30 dishes contained females and larvae. Three dishes (7-9) each contained well over 100 ants. In each case the eggs were missing and all that remained of the female was a skeleton (Fig. 1-B).

I placed masking tape over the ventilation holes of one of the dishes to prevent the ants from escaping. I then returned to the Highlands Biological Station where I confined a living female in the ant-infested dish. Within five minutes the female was dead.

There can be no doubt that predaceous ants represent a potential threat to brooding females and their

eggs, but the frequency with which such encounters occur remains unclear. In nature, attending salamanders and their eggs are localized along the margins of streams and thus could be easily located by searching ants. However, since all three of the confinement dishes entered by the ants were situated in close proximity to one another (20-80 cm apart), and since ants did not enter other dishes located up and down stream, it is likely that the recorded predation was the result of chance discovery and the inability of the female to escape from the dish.

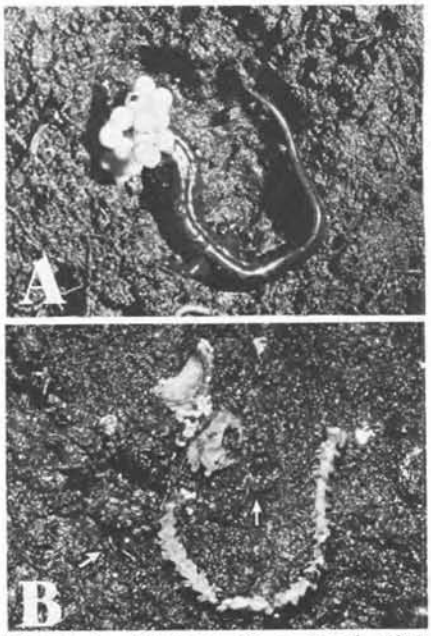

Figure 1. Closeup of a petri dish containing: (A) an attending female and her eggs; (B) the skeletal remains of a female consumed by predaceous ants (arrows indicate the location of ants).

ACKNOWLEDGMENTS

The ants were identified by T. P. Nunn, Department of Entomology, North Carolina State University. The observations on ant predation were made while the author was supported by a predoctoral grant-in-aid from the Highlands Biological Station, Inc.

An Unusually Patterned Specimen of the Gray-Banded Kingsnake, Lampropeltis mexicana alterna (Brown)

Descriptions of aberrations in the color patterns of a variety of North American snake genera have appeared in the literature. Anomalous features have been most frequently reported for the genus Crotalus (Gloyd, 1935, 1958; Klauber, 1972; Nickerson and Mays, 1968), but genera such as Agkistrodon, Elaphe, Lampropeltis, Pituophis, Thamnophis and others have been shown to include specimens with color or pattern deviations (Gehlbach, 1962; Gloyd, 1958; Hensley, 1959; Fitch, 1959). Many examples previously recorded have been albinistic or melanistic (Hensley, 1959; Klauber, 1972), but occasional specimens are found with stripes replacing the normal blotched pattern or some other pattern defect. Fitch (1959) described specimens of Agkistrodon contortrix which were completely devoid of dorsal pattern.

Atypical color or patterns have been reported for three species of the genus Lampropeltis. Blanchard (1921) and Ashton (1973) reported striped examples of the normally blotched L. c. calligaster, and Blaney (1977) reviewed earlier accounts of abnormally patterned L. getulus. Williams (1978) discussed various anomalies in L. triangulum, including an albino specimen of L. t. triangulum (Condit and Woodruff, 1955), and an aberrant specimen of L. t. celaenops possessing deviations in both color pattern and scutellation (Gehlbach, 1962). Williams (1978) also noted specimens of L. t. triangulum and L. t. annulata with tendencies toward partial striping.

Although it is a species prone to extreme variability (Gehlbach, 1967; Gehlbach and Baker, 1962; Tanzer, 1970; and others), previous reports of atypically colored or patterned specimens of the gray-banded kingsnake, L. mexicana alterna are unknown in the literature; however, Frank Retes (personal communication) reported an individual with dorsal striping. This paper describes an unusual specimen of this form.

The specimen, a male blairi phase (Tanzer, 1970) L. m. alterna (total length 281 mm, tail length 38 mm, weight 10.9 g at hatching) hatched 25 August 1977 as the result of a captive breeding between two typically patterned blairi phase kingsnakes. Both were collected near Langtry, Val Verde Co., Texas, September, 1972 (male) and June, 1973 (female). From a total of sixteen hatchlings from this pair (described, in part, by Murphy et al., 1978) and eighteen additional hatchlings from the female, this was the single obvious anomaly. The male parent (UTA-R7188) is in the vertebrate collection of The University of Texas at Arlington. The female and the presently described specimen are being maintained alive in the collection of the author. I am indebted to J. S. Dobbs and Dennis W. Herman for depositing specimens for my use. James B. Murphy kindly read and commented on the manuscript.

Visually, the specimen is quite striking. Overall coloration is that of a light blairi morph with an infusion of black pigment. The head and snout are black, lower labials dark gray lightening to medium gray on the throat. The iris is dark brown and the tongue is black. The venter is black but gray patches invade the length of the body and tail slightly from both sides. A black stripe 4-6 scales wide connects to the parietals middorsally and extends to the left where it widens irregularly to the right and splits where red pigment begins.

Anteriorly, the majority of red is confined laterally to the left. The first series of normal bands are replaced by a red stripe 2-14 scales wide extending 33 percent of the total length from the ventrals to the sixth scale row. This stripe is expanded in four areas but in only three does red pigment extend across the middorsal line. Wide areas of black outline all red areas of the striping, but in the first and second expansion, the black extends as a band dorsolaterally to the right side of the ventrals. Irregular black blotches (2-4 scales) are present in gray interspaces posterior and anterior to these black bands, giving the impression of alternating markings and perhaps indicating where normal banding should occur.

The second and third bands are joined laterally on the left as are the fifth and sixth bands. Red scales are present in these bands, but in only the second does red pigment cross middorsally. The fourth and bands seven through twelve are single. In the fifth band, red scales are restricted laterally to

Fig. 1. Atypically patterned Lampropeltis mexicana alterna hatched 25 August 1977.

the left, while in the remaining body bands, red scales extend dorsolaterally to the right but remain generally restricted laterally to the left. There are four black tail bands, the first of which contains red scales. The tail tip is black. On the left, in addition to the first black band anteriorly, black bands extend dorsolaterally to the ventrals in the second, fourth, fifth, sixth, seventh, eighth, and tenth through twelfth bands. All black areas dorsally and laterally, including the irregular blotches anteriorly, are outlined with 1-2 scales of white.

Overall, the entire pattern appears shifted to the left (Fig. 1). Therefore, if viewed from the left, the specimen appears as an atypical blairi morph, and from the right, with a reduction of red pigment, it bears a strong resemblance to the alterna morph of L. mexicana alterna.

Scutellation, however, is quite normal and all counts fall within the range for blairi and alterna morph L. m. alterna (Gehlbach, 1967; Gehlbach and Baker, 1962). Ventrals are 217, subcaudals 62, and dorsal scale rows immediately anterior to the anal plate are 25, 27, and 19, respectively. Upper labial counts are 7, and lower labials number 10 for both sides. Preocular-postocular counts are 1-2 on the left and 1-3 on the right. Possible skeletal abnormalities were not determined, although feeding and other normal activities were not restricted.

Although the deviation from pattern symmetry and the apparent assumption of blairi and alterna affinities on the left and right, respectively, is interesting, this comparison is in no way intended to imply that this specimen is an intermediate. So called intermediate specimens have been described previously (Gehlbach and Baker, 1962; Tanzer, 1970) on the basis of such characteristics as length and width of the nuchal blotch or band, the degree of or the absence of red (or orange) pigmentation, the number of major body bands, and the presence or absence of alternating markings between major body bands. It can be seen, however, with the present number of specimens available for study, that certain of these characters do not, as once throught, indicate particular affinities. For example, alternating markings can no longer be used to affirm alterna morph affinities, as successive captive-breedings of blairi morph specimens possessing dorsal alternating markings have failed to produce alterna morph snakes. In addition, alterna phase specimens are known with few or no alternating markings from certain parts of their range. Variations of a single character should rarely if ever be used to determine affinities, particularly when few specimens are available.

It is unfortunate that many of the previously reported "aberrant" specimens were determined so on the basis of a single anomalous character (i. e., melanism, color of stripes or bands, striping instead of blotching, etc.). In some cases, these early reports were later shown to be typical of a population within a certain range (Blaney, 1977). In others, as in the described specimen, it is nothing more than the atypical individual that may appear sooner or later in any given population.

A Record of a Breeding Amelanic Loggerhead Turtle

Albinism has been reported infrequently among sea turtle hatchlings (Chelonia mydas (L.): Bustard, 1972; Carr, 1967; Harrison, 1963. Caretta caretta (L.): Hughes, 1974). However, neither these authors nor Gilboa and Dowling (1974) make any reference to albino adult sea turtles.

An amelanic loggerhead turtle, Caretta caretta, was observed nesting on Wreck Island, south Great Barrier Reef, Queensland, Australia. Carapace measurements over the curve were: midline length 101 cm, maximum width 91 cm ($\bar{x}$ mature female C. caretta curved carapace length = 96 cm, range 80-112 cm). The scutes of the carapace, plastron and head were yellowish, while the skin was white, although when first seen, the thick algal coating obscured much of the carapace coloration. It was observed laying on 23 December 1977 and 20 January 1978. On the latter date, the clutch size was 109 eggs. Six eggs from this clutch were returned to the laboratory for incubation and four hatched, giving normally pigmented young.

At nearby Mop Repos rookery on mainland south Queensland, loggerhead turtles have been the center of research for ten summers. There, no amelanic hatchling has been found among over 73,000 hatchlings examined on the beach. However, examination of the nests from which these hatchlings emerged occasionally revealed amelanic embryos and/or hatchlings remaining after the emergence of normally pigmented siblings. Albinism in these instances was usually associated with varying degrees of deformity of the carapace and/or head. The amelanic embryos often lacked the caruncle, and so could not cut their way from the eggs, where they would thus die. Amelanic hatchlings were usually smaller and less active than normal and all those found via nest excavation were expected to die in the nest.

That an amelanic turtle should emerge from the nest is unusual. That such a turtle survived to reproductive maturity in the wild seems remarkable. This is the only amelanic turtle recorded among approximately 5,400 nesting loggerhead turtles and 300 others (immatures to adults) tagged in eastern Australia within the Queensland Turtle Research Project since 1968.

The normally pigmented offspring suggest a mating with a normally colored male and indicate that amelanism in this species is a recessive character. Further, it would appear that normal coloration is not a necessary cue for female recognition by the courting male loggerhead turtle.

Dicephalism in the African Worm Snake Leptotyphlops bicolor

Dicephalism is a rare form of abnormality, but because of its bizarre nature is one that usually commands public attention. Two-headed snakes have been known since the time of Aristotle, although Cunningham (1937) was the first to study the pathology in depth, compiling a list of over 80 cases, of which no less than 33 were from the colubrid genus Natrix. Since his exhaustive study, additional examples have been described at infrequent intervals in the literature (Vanzolini, 1947; Shaw and Campbell, 1974; Davies, 1974). Klauber (1956), as he did with all other aspects of the biology of rattlesnakes, thoroughly reviewed the occurrence of dicephalism in the group.

The vast majority of dicephalic reptiles have been reported from North America and Europe, with very few examples coming from Africa (Broadley, 1972). However, this is unlikely to represent regional differences in the frequency of the abnormality, but rather, reflects the prevalence of herpetologists in these areas!

While reviewing Nigerian Leptotyphlops housed in the British Museum (Natural History) collections, I discovered a two-headed specimen of Leptotyphlops bicolor. Although collected in 1938, to my knowledge the existence of this specimen has not previously been noted. It is of interest in representing the first record of dicephalism in a scolecophidian, while the size of the specimen suggests that it must have survived for some time after hatching.

The snake (BM 1938.3.1.77) was collected at Lokoja, Kobba Province, Southern Provinces, Nigeria, by J. H. Pasqual, and has two perfectly formed heads, of almost equal size (Fig. 1). The right head (when viewed from above) forms a continuous axis with the main body, from which the left head protrudes at almost 90^0. The heads are of equal width, but the left head is slightly shorter (5 mm) than the other (6.8 mm). All details of scutellation for both heads are as for typical bicolor (Villiers, 1975), with the exception that the first and second supralabials are fused on the right side of the left head. Including the rostral, the right head has 19 dorsals to the point of fusion, compared with 16 dorsals along the left head. Posterior to the fusion, there are 240 dorsals, 9 subcaudals, and a terminal spine. The scales are in 14 rows at mid-body, and the snake measures 91 mm from the snout of the right head to the terminal spine. On the ventral surface, 76 dorsals from the tail tip, two ventrals are split in the mid-line, and may represent the remains of the umbilical scar.

Villiers (1975) lists the average length of L. bicolor as 125-150 mm, although Leston and Hughes (1968) record a female of 187 mm from Tafo, Ghana. Eleven specimens from Nigeria in the BM collection range in length from 72-171 mm.

Although the majority of two-headed snakes die at or shortly after birth, others survive for some time. Because of its size, the dicephalic L. bicolor, although not an adult, is unlikely to be a hatchling, and must presumably have survived, fed and grown for some time after hatching. Captive two-headed snakes have occasionally survived for long periods, and perhaps the most famous of these was "Dudley Duplex", a California king snake (Lampropeltis getulus) that survived for six and a half years at San Diego Zoo (Shaw and Campbell, 1974). However, Leptotyphlops are specialized fossorial termite-eaters, and it is intriguing to wonder how a two-headed fossorial snake could successfully search for food in the wild.

ACKNOWLEDGMENTS

I am grateful to Miss A. Grandison, British Museum of Natural History, for allowing me to study specimens in her care.

An Inexpensive Method of Construction for Enclosures and Fences

Most enclosures and fences used by herpetologists have been constructed using either lengths of hardware cloth topped by a second horizontal piece or lengths of galvanized metal sheeting (Medica et al., 1971; Lotter, 1975). While such structures have the advantage of imperviousness to weather and are durable over long periods of time, the disadvantages of high initial cost and difficult construction often preclude use, especially by less affluent herpetologists. However, another type of fence can be constructed cheaply and easily, and is both fairly resistant to weather and sufficiently durable for most studies.

The fence is constructed of clear polyethylene plastic approximately 10 mils thick. Although it is easier to purchase the plastic in precut widths, I found it much cheaper to buy it in larger widths and cut it myself. The fence is supported by 1" x 2" pine stakes commonly used as highway markers. Both the stakes and plastic may be purchased from most lumber retailers.

The stakes are hammered into the ground wherever the fence is to be located. The plastic is stretched between the stakes and stapled directly to them. I found it useful to place a piece of electrical tape on top of the plastic adjacent to the stake and then staple through the tape; this gives added support at stapling points. The bottom of the plastic is then either buried to the desired depth or laid flat on the ground and covered with rocks and dirt.

This type of fencing is useful for drift fences and enclosures. It will also prove very useful for those working in remote areas since it is considerably lighter than metal. The facing will last a reasonable time with only minor maintenance. I found the electrical tape useful for repairing rips, and only occasionally found it necessary to replace sections. With only minor repairs, the fencing will last many months, but continued exposure to thermal extremes will effect the plastic's resiliency, a problem I especially noted after 18 months. Black polyethylene is more susceptible to this; in addition, the clear plastic is much less noticable. The approximate cost for this type of fencing is less than 10 cents per running foot.

SOURCES OF AMPHIBIANS FOR RESEARCH, II.

The frequent requests for a wide variety of amphibian species and the absence of a clearinghouse for information on sources of amphibians led to the publication in 1971 of a list of suppliers (Nace, Waage, and Richards, 1971). The ink was not dry before that list required amendments. Now, six years later, the renewed press of inquiries leads us again to publish such a list. Several attempts were made to contact each source on the previous list, and only those who reported they were active as of October 1977 appear here. The original list cited 59 sources. This new list cites 64, but of these only 27 were on the original list. The first list named sources for 144 species; this list names 195 species.

These statistics might suggest that although sources change, the supply of amphibians is fairly constant. This, however, would be an incorrect conclusion: there have been many changes in amphibian supply during this six-year period.

Dominating the period was a marked change in the availability of animals in the leopard frog group. In the early 1970s, virtually all leopard frogs used in teaching (13,000,000) and research (2,000,000) (Nace, 1970; Gibbs, Nace, and Emmons, 1971) were captured in the wild. Now, nature no longer can meet the need (Nace, Culley, Emmons, Gibbs, Hutchison, and McKinnell, 1974; Wake et al., 1975; unpublished NIH conference of 1975). Thus, one commercial supplier (Emmons, personal communication) reports that in 1970-71 they processed over 10 *tons* of leopard frogs from one western state alone, whereas in 1974-75, less than 250 *pounds* of these frogs were available (Nace, 1976a). Even commercial frog catchers with 30-40 years of experience come up empty-handed (McKinnell, personal communication), and in a recent study of about 75 known breeding sites in Wisconsin, egg clutches were found at only five (Hine, Les, Hellmith, and Vogt, 1975). This reduction in the number of breeding sites was accompanied by reduced fertility rates for the eggs which were laid. During this same period a population near Ann Arbor, Michigan dropped from 85,000 leopard frogs to *zero* (Nace, 1977).

Such changes in commercially exploitable populations of leopard frogs have been widespread and apply equally to other anura throughout the world. How many species have been affected is unknown. The causes for these population declines seem to be multiple (Cooke, 1972) and although reports from commercial suppliers in the fall of 1977 suggest a stabilization of the situation, they do not signal an improvement. In the face of these circumstances, the laws of supply and demand have forced a rapid increase in commercial prices for frogs ($2.25 per dozen for 3-inch *Rana pipiens* in 1972 from one company compared with $10.00 in 1977 from another), a pressure to shift to new teaching organisms such as the fetal pig (Nace, 1976b), and domestically raised *Xenopus* (Eldridge, 1976), and, apparently, a sharp reduction in the exposure of students to live vertebrates.

A second change during this period has been the acquisition of the major family-enterprise commercial frog supply houses, whose proprietors were in personal contact with the frog catchers, by large suppliers of educational materials. This has been accompanied by reduced contact with the frog catchers. Even had the supply of frogs in nature remained unchanged, this new structure of the industry would have reduced the accessible supply of animals. Although many of the individuals have changed, a second category of suppliers remains constant. These are the investigators and "hobbyists" who are willing to share their resources with others. Among these, some are able to provide limited services gratis, whereas others, because of the demand and for institutional reasons, must charge for their services.

A third change during this period is evident in the research use of amphibians. Nace (1968, 1970, 1976a, 1976c) and Gibbs, et al., (1971) called for improvement in the quality of the amphibians used in research. This improvement was badly needed in the areas of systematic definition, disease, nutritional and genetic control, and in-house care of the animals (see Symposium, 1973). Concurrently, the changing status of many research areas including neurology (Fite, 1976, Llinás and Precht, 1976) and nuclear transplantation (McKinnell, 1978) has occasioned an increasing demand for amphibian models with genetic definition and genetic markers.

Important events in the improvement of amphibian standards have included work on the systematic definition of the popularly used leopard frogs. Because the reevaluation of the species in this complex by Pace (1974) is of great utility and importance to the potential users of this list of sources, her description and key to these species is reproduced here:

Rana pipiens Schreber

This is probably the most widely ranging member of the species complex. It is the only leopard frog known in Canada. In the United States it is found in New England, in New York and Pennsylvania, in most of Ohio and northern Kentucky, in northern and central Indiana, in northern Illinois, in Iowa and west to and through the Rocky Mountains. In the Far West it is found in the Snake River Valley, the Columbia River Valley, and in Lake Tahoe and other areas of California and Nevada. It is also found at higher elevations at least as far south as Alpine, Arizona, and may occur in at least the northern part of Mexico as well.

Rana utricularia Harlan

Found throughout most of the Atlantic Coastal Plain from southern New York and northern New Jersey and through the Gulf Coastal Plain to somewhere between Corpus Christi and Victoria, Texas. It is found in southern Missouri, southern Illinois, southwestern Indiana, most of Kentucky, and extreme southern Ohio. It is found in southeastern Kansas and eastern Oklahoma and is the only leopard frog known from Tennessee, Arkansas, Louisiana, Mississippi, Alabama, Georgia, Florida, South Carolina, North Carolina, Virginia and Delaware.

Rana berlandieri Baird

In the United States this species is known only from southern Texas. It is known from as far north as Johnson County, in central Texas, and San Patricio County, along the Gulf Coast. It may also occur west of the Pecos River (known from Ward County, Texas, whose western border lies along the Pecos River).

Rana blairi Mecham, Littlejohn, Oldham, Brown and Brown

Found in the central plains and prairie regions of the United States, from eastern Colorado, northeastern New Mexico, northern Texas, Oklahoma (except the southeastern third of the state), most of Kansas, part of Nebraska and Iowa, and in northern Missouri, central Illinois, and in scattered localities further east (western Indiana) and south (southern Illinois).

Key to Adult Males in the *Rana pipiens* Complex from the United States (from Pace, 1974)

1. Skin at angle of jaw overlying internal vocal sac not differentiated in texture or color from surrounding skin (may be somewhat stretched); no distinct white spots on centers of tympana; dorsolateral folds continuous and not displaced, usually wide and low, but discernible to the point where the leg joins the body; dorsal spots usually ringed with light coloration . . . . . *Rana pipiens*

1'. Skin at angle of jaw overlying internal vocal sac differentiated from surrounding skin in some way (e.g., texture or pigmentation); tympanal spots, dorsolateral folds, and dorsal spots variable 2

2(1'). Mullerian ducts absent, or specimen from Florida 3

2'. Mullerian ducts present and specimen from Texas. . . . *Rana berlandieri*

3(2). External vocal sacs large, spherical, apparently thin-skinned, lying loose at angle of jaw when not inflated or from Florida; dorsolateral folds usually continuous and not displaced . . . . . *Rana utricularia*

3'. External vocal sacs small, usually visible only because skin at angle of jaw is conspicuous when internal vocal sac is not inflated owing to texturings of the skin below the labial stripe; dorsolateral folds usually discontinuous and displaced medially. . . . . *Rana blairi*

It is unfortunate that no key is available for the females of these species. Also, please note that some systematists prefer *R. sphenocephala* to *R. utricularia*. Of additional importance is the recent work on the leopard frogs of the Southwest and Mexico by Frost and Bagnara (1976). However, few, if any, commercial suppliers are prepared to distinguish among any of these species of leopard frogs when they provide "*Rana pipiens*." Indeed, some suppliers attempt to meet demands with frogs imported from Europe, and this may not always be indicated on the packing slips. Thus, the

user is urged to exercise caution regarding the identity of amphibians used in research protocols (Bagnara and Frost, 1977).

Another event of importance in defining research amphibians and their use was the appearance of "Amphibians: Guidelines for the breeding, care and management of laboratory animals" (Nace et al., 1974). Although already out of date in some particulars, this document remains the best currently available source of information on the matters suggested by its title. Of particular note, it defines a nomenclature for a classification to permit investigators to select animals most appropriate to their needs, to communicate effectively with suppliers, and to accurately report their data. This nomenclature is reproduced here for the reader's convenience, but the reader is urged to become familiar with the definitions of these terms as given on pages 27-36 of the reference.

1. Wild
2. Wild-caught
   a. Wild-caught nonconditioned
      (1) Wild-caught nonconditioned nontreated
      (2) Wild-caught nonconditioned treated
      (3) Wild-caught nonconditioned miscellaneous
   b. Wild-caught conditioned
      (1) Wild-caught conditioned larvae
      (2) Wild-caught conditioned juveniles or adults
      (3) Wild-caught conditioned miscellaneous
3. Laboratory reared
   a. Laboratory-reared standard
   b. Laboratory-reared miscellaneous
4. Laboratory bred
   a. Laboratory-bred standard
   b. Laboratory-bred miscellaneous

Among laboratory-reared and laboratory-bred animals the following types of populations and lines may be designated:

(1) Random mating lines
(2) Heterozygous isogenic clones
(3) Heterozygous marked lines
(4) Mutant lines
(5) Inbred lines
(6) Gynogenetic diploid lines
(7) Homozygous lines
(8) Haploid animals
(9) Polyploid animals

Attention is also directed to Müller (1976) which on a comparative basis details many experimental parameters of concern to those using amphibians for research and describes the useful series of books on amphibian physiology represented most recently by Lofts (1976).

Among the sources cited in the following list, those marked with "§" are, at present, adhering to the conventions of this classification, and #39 is developing the capacity to do so.

The provision of animals with genetic definition or genetic markers is most advanced at the Axolotl Colony (#3) (Malacinski and Brothers, 1974), as might be expected from the long history of culture of the Mexican axolotl. Attention of the readers is drawn to the informative Axolotl Newsletter available from that resource. Other species for which there has been significant development of genetic definition are *Xenopus laevis* and *Pleurodeles waltlii*. Although at this time no specific sources can be cited for genetically defined stocks of these animals, they are available on occasion from the investigators using them. Among the ranids, the best stock of genetically significant animals is held by the Laboratory for Amphibian Biology, Hiroshima, (#27) and to a lesser extent by the Amphibian Facility.

A major problem in providing high-quality animals to users has been the inadequacy of the care in users' laboratories. Basic to this has been inappropriate housing. The development of housing units that would reduce labor and space costs, promote the health of animals, and be adaptable to a wide variety of species has been a major concern of the Amphibian Facility. Such units are now available and feature a highly adaptable enclosure (amphibians are not held in aquaria, terraria, cages, or pens) called the Michigan Environmental Enclosure for Small Animals (MEESA) and include an Adjustable Depth Overflow Pipe (ADOP). Figure 1 shows a two-enclosure model made of plastic and Figure 2 shows a six-enclosure unit made of stainless steel. The Amphibian Facility has recently been remodeled and animals are housed in these enclosures mounted on five-tier racks. If these enclosures are used, nearly all aspects of the environment may be controlled. The units are manufactured by Keyco Co. (P.O. Box 12, Peach Bottom, Pennsylvania, 17563, 717-548-2185, Mr. Howard Fricke, President) and are currently marketed by NASCO (#37). We also call the reader's attention to the new enclosures for bullfrogs developed by Culley (1977).

The Amphibian Facility continues to develop and provide laboratory-reared and laboratory-bred amphibians as research animals for the scientific community. As of October 1977, the colony is composed of over 10,000 living, postmetamorphic animals. This number is not sufficient to permit distribution of large quantities of adult animals to many investigators. However some adults can be provided on a selected basis, and tadpoles of almost any stage are available throughout the year. Arrangements can also be made for other services as described in a price list which may be obtained on request.

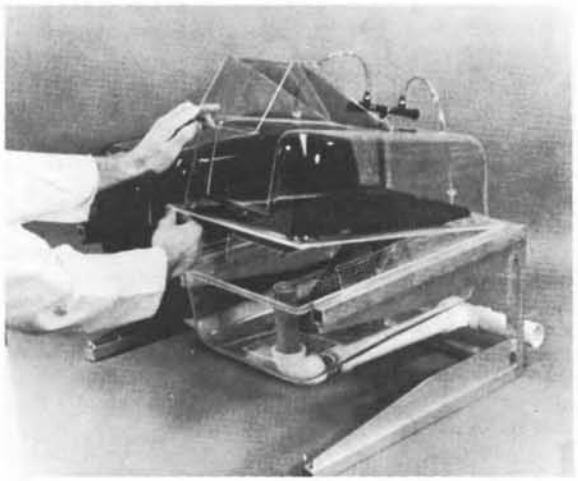

Figure 1. A two-enclosure table top, plastic model of MEESA suitable for carrying up to 150 mature *R. pipiens* for several weeks and 50 indefinitely in each enclosure. Modular units may be added. It can also house all other species of amphibians as well as fish, lizards, snakes, and small mammals or birds. Temperature, water, air flow, and light can be controlled.

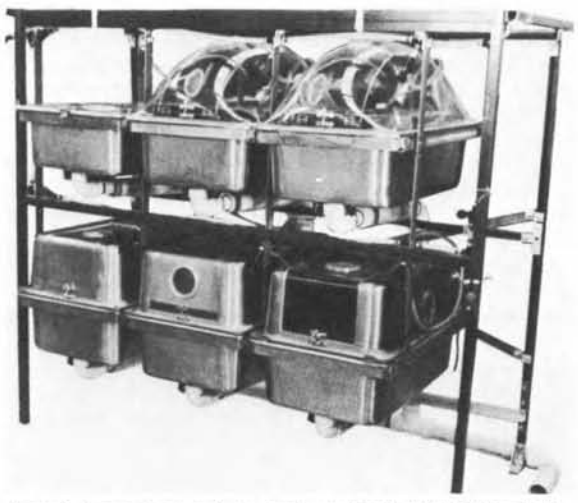

Figure 2. A six-enclosure, stackable, stainless-steel model of MEESA showing several alternative configurations. Stainless steel is used to avoid plasticizers.

The Amphibian Facility can provide *Xenopus laevis*, *Bombina orientalis*, and *Hyperolius* sp., but its major focus continues to be Northern *Rana pipiens*. It is to be noted that a major realization

in the past several years has been that although the life cycles of ranids from more temperate areas seem quite amenable to control as revealed by their culture at the Laboratory for Amphibian Biology, Hiroshima, by Bagnara (personal communication) at Tempe, Arizona, and at the Amphibian Facility, the Northern *R. pipiens* and *R. catesbeiana* are particularly refractory. Progress is being made on both species, however, and we have succeeded in bringing Northern *R. pipiens* to maturity in 8 months, compared with 24 to 36 months in nature, and progress has been reported on work with *R. catesbeiana* (Culley, 1977).

Two commercial concerns, one over three years old (Xenopus Ltd., #60) and one currently becoming established (Ozark Amphibian Center, #39), have adopted Amphibian Facility techniques in their attempts to provide service to the scientific and teaching communities. Thus, although the recommendations of the Sub-Committee on Amphibian Standards, Committee on Standards of the National Research Council (Nace et al., 1974) and the Committee on Herpetological Resources (Wake, et al., 1975) regarding frog culture will not be fully satisfied immediately, there is reason to believe that within the next few years amphibian culture will contribute to the alleviation of the demand for amphibians in a much more significant way than seemed possible six years ago.

Regarding the list of suppliers, it will be noted that no prices or statements concerning the availability or conditions under which these animals can be supplied are included in this list. Also, the species are listed as given by the supplier. We have not attempted to review the taxonomic validity of the terms. The supply and developmental stage of animals from all sources are subject to seasonal and other factors which are generally beyond the control of the supplier. Particularly difficult in recent years has been the problem of transportation. Deterioration in the services of the U.S. Postal Service and vagaries in the use of commercial transport concerns have added to the cost and difficulty of transporting animals. Users are urged to communicate directly with the listed sources to obtain the necessary purchasing or exchange information as well as the details concerning the availability of materials.

Animals Available from Specified Suppliers

Anurans (frogs and toads)

BUFONIDAE

Bufo sp. 35, 43, 63
B. alvarius (Colorado river toad) 35, 51
B. americanus (American toad) 5, 13, 20, 30, 37, 51, 55, 56, 59, 60, 62
B. angusticeps 54
B. asper (hill toad) 35
B. blombergi (Blomberg's toad) 5, 35
B. boreas (Western toad) 5, 19, 51, 59, 60
Bufo bufo (common toad) 5, 23, 35, 50, 59, 60
B. calamita (Natterjack) 51
B. cognatus (Great Plains toad) 5, 51
B. compactilis (Texas toad) 51
B. debilis (green toad) 5, 51
B. gariepensis 54
B. guercicus 5
B. marinus (marine or giant toad) 5, 9, 34, 35, 36, 37, 40, 41, 49, 50, 51, 52, 55, 56, 58, 60, 62
B. mauretanicus (Berber toad) 35
B. melanostictus 35
B. pardalis 47, 54
B. poweri (garden toad) 5
B. punctatus (red-spotted toad) 5, 51
B. quercicus (oak toad) 51
B. rangeri 54
B. regularis (African squareback toad) 33, 35, 47
B. rosei 54
B. terrestris (Southern toad) 5, 35, 51, 60
B. valliceps (Gulf Coast toad) 5, 51
B. viridis (green toad) 5, 35, 60
B. woodhousei (Woodhouse or Fowler's toad) 5, 13, 30, 35, 51, 60

DENDROBATIDAE

Dendrobates auratus (arrowhe d poison frog) 19

DISCOGLOSSIDAE

Alytes obstetricans (midwife toad) 51, 60
Bombina sp. 63
B. bombina (fire-bellied toad) 18, 19, 35
B. orientalis (bell frog) 1, 27, 60
B. variegata (yellow-bellied toad) 35, 60
Discoglossus pictus (Spanish painted frog) 35

HYLIDAE

Acris blanchardi (Blanchard's cricket frog) 51
A. crepitans (Northern cricket frog) 5, 51
A. gryllus (Southern cricket frog) 5, 51
Agalychnis dachnicolor 19, 49
Hyla sp. 16, 36, 43, 49
H. arborea (European treefrog) 18, 35, 50, 51, 60
H. arenicolor (canyon treefrog) 35, 51
H. avivoca (bird-voiced treefrog) 51
H. cadaverina (California treefrog) 51
H. chrysoscelis (Southern grey treefrog) 51
H. cinerea (green treefrog) 5, 19, 23, 30, 35, 46, 49, 51, 60
H. crucifer (spring peeper) 5, 13, 51, 60
H. femoralis (pine wood treefrog) 51
H. gratiosa (barking treefrog) 5, 19, 35, 51
H. regilla (Pacific treefrog) 19, 35, 51, 59
H. septentrionalis (Cuban treefrog) 9 51
H. squirella (squirrel treefrog) 5, 51
H. vasta (giant treefrog) 9
H. versicolor (common or gray treefrog) 5, 13, 19, 35, 51, 60
Limnaoedus ocularis (little grass frog) 51
Phrynohyas venulosa 19
Pseudacris brachyphona (mountain chorus frog) 51, 60
P. clarki (spotted chorus frog) 5, 51
P. nigrita (chorus frog) 5, 51
P. ornata (ornate chorus frog) 5, 51
P. streckeri (Strecker's chorus frog) 51, 60
P. triseriata 5, 51

LEPTODACTYLIDAE

Ceratophrys calcarata (horned frog) 9, 35
Eleutherodactylus ricordi (green-house frog) 51
Heleophryne sp. 54

MICROHYLIDAE

Breviceps sp. 54
Gastrophrynae carolinensis (Eastern narrowmouth toad) 51
Gastrophrynae olivacea (Western narrowmouth toad) 51
G. carolinensis 5
G. olivacea 5
G. variolosus 5
Kaloula pulchra 19, 35

PELOBATIDAE

Pelobates fuscus 63
Scaphiopus sp. 35
S. hombifrons (plains spadefoot toad) 51, 60
S. couchi (Couch's spadefoot toad) 35 51
S. hammondi (Western spadefoot toad) 51
S. holbrooki (Eastern spadefoot toad) 51, 60
S. hurteri (Hurter's spadefoot toad) 51

PHRYNOMERIDAE

Phrynomerus sp. 35
P. bifasciatus (red-backed frog) 54

PIPIDAE

Pipa pipa (Surinam toad) 35
Xenopus borealis (Kenyan clawed toad) 60
X. gilli 5, 54
X. laevis (South African clawed toad) 1, 2, 5, 14, 16, 21, 23, 28, 29, 33, 36, 37, 38, 39, 40, 44, 47, 49, 50, 51, 54, 60
X. laevis (periodic albinism) (South African clawed toad) 1, 28, 44
X. mulleri 44
X. tropicalis (Nigerian clawed toad) 60

RANIDAE

Arthroleptella sp. 54
Cacosternum capense 54
Ptychadena anchietae (Savanna sharp-nosed frog) 33
P. mascareniensis (green-striped frog) 33
Pyxicephalus adspersus 19, 54
P. delalandii 54
Rana sp. 16, 54, 62
R. adspersa (African bullfrog) 5, 33
R. areolata (crawfish frog) 5, 51
R. berlandieri (Rio Grande leopard frog) 1, 51
R. blairi (plains leopard frog) 1, 5, 51
R. capito (gopher frog) 51
R. catesbeiana (bullfrog) 5, 7, 10, 11, 12, 12a, 13, 15, 16, 20, 22, 25, 30, 31, 31a, 34, 35, 36, 37, 38, 40, 41, 43, 45 46, 48 49, 51, 53, 57, 58, 59, 60, 61, 62
R. catesbeiana x *R. grylio* 7
R. clamitans (green or bronze frog) 5, 24, 34, 35, 36, 37, 38, 46, 51
R. esculenta (edible frog) 18, 23, 32, 50, 60, 63
R. graeca 18
R. grylio (pig frog) 5, 7, 25, 49, 51
R. heckscheri (river frog) 5, 51
R. japonica 27
R. nigromaculata 27
R. occipitalis (groove-crowned bullfrog) 33
R. palustris (pickerel frog) 5, 35, 51, 60
R. pipiens (leopard or grass frog) 1, 5, 6, 8, 10, 12, 12a, 13, 16, 20, 22, 23, 24, 25, 26, 29, 30, 34, 35, 36, 37, 38, 39, 40, 42, 43, 48, 49, 53, 55, 56, 58, 59, 60, 62
R. ridibunda (marsh frog) 60
R. septentrionalis 5
R. sylvatica (wood frog) 5, 13, 35, 51
R. temporaria 23, 24, 59, 60, 63
R. tigrina 16
R. utricularia (sphenocephala) (Southern leopard frog) 1, 5, 51

RHACOPHORIDAE

Chiromantis petersi 35
Hyperolius sp. 1, 33, 35, 54
Kassina senegalensis (African walking frog) 35

Urodeles (salamanders and newts)

AMBYSTOMATIDAE

Ambystoma sp. 5, 19, 34, 43, 48
A. annulatum (ringed salamander) 51
A. cingulatum (frosted flatwoods salamander) 51
A. jeffersonianum 5, 35, 51, 60
A. maculatum (spotted salamander) 5, 13, 35, 36, 51, 60
A. mexicanum (Mexican axolotl) 1, 3, 4, 17, 23, 28, 60
A. opacum (marbled salamander) 5, 35, 51, 60
A. talpoideum (mole salamander) 51, 60
A. texanum (small-mouthed salamander) 5, 35, 51
A. tigrinum (tiger salamander) 5, 20, 24, 30, 35, 36, 38, 50, 51, 59, 60, 62

AMPHIUMIDAE

Amphiuma sp. (Congo eel) 5, 8, 25, 30, 36, 46, 48, 49, 59
A. means (two-toed amphiuma) 51, 60
A. tridactylum (three-toed amphiuma) 51

CRYPTOBRANCHIDAE

Cryptobranchus alleganiensis (hellbender) 51
Megalobatrachus japonicus (giant salamander) 35

PLETHODONTIDAE

Aneides aeneus (green salamander) 51
A. ferreus (clouded salamander) 51
A. flavipunctatus (speckled black salamander) 51
A. lugubris (arboreal salamander) 51
Batrachoseps attenuatus (California slender) 51
B. major (garden slender salamander) 51
Desmognathus auriculatus (Southern dusky) 51
D. fuscus (dusky salamander) 35, 51
D. monticola (seal salamander) 35, 51
D. ochrophaeus (Blue-Ridge Mt. salamander) 35, 51
D. quadramaculatus (black-bellied salamander) 35, 51, 60
D. wrighti (pigmy salamander) 51
Ensatina eschscholtzi (Monterey salamander) 51
E. xanthoptica (yellow-eyed salamander) 51
Eurycea bislineata (two-lined salamander) 13, 35, 51
E. longicauda (longtailed salamander) 35, 51
E. lucifuga (cave salamander) 35, 51, 60
Gyrinophilus danielsi (Blue Ridge Mt. spring salamander) 35, 51
G. dunni (Carolina spring salamander) 51
G. porphyriticus (Northern spring salamander) 5, 35, 51
Hemidactylium scutatum (four-toed salamander) 51
Leurognathus marmoratus (shovelnose salamander) 51
Manculus quadridigitatus (dwarf salamander) 51
Plethodon cinereus (red-backed salamander) 5, 13, 35, 51
P. dorsalis (zig-zag salamander) 5, 35, 51
P. glutinosus (slimy salamander) 5, 35, 51
P. jordani (red-legged salamander) 51
P. richmondi (ravine salamander) 51
P. welleri (Weller's salamander) 51
P. yonahlossee (Yonahlossee salamander) 51
Pseudotriton diastictus (midland mud salamander) 51
P. floridanus (rusty mud salamander) 51
P. ruber (red salamander) 5, 35, 51, 60
P. schenki (black-chinned red salamander) 51
P. vioscai (Southern red salamander) 51

PROTEIDAE

Necturus sp. 16, 34, 37, 38, 46, 48, 53, 55, 56, 59
N. maculosus (mud puppy) 5, 8, 12, 12a, 13, 20, 24, 35, 36, 50, 51, 60

SALAMANDRIDAE

Cynops pyrrhogaster (= Triturus pyrrhogaster) (Japanese fire-bellied newt) 27
Diemictylus perstriatus (striped newt) 51
Notophthalmus viridescens (= Triturus or Diemictylus viridescens) (red-spotted newt) 5, 8, 13, 20, 36, 51, 55, 56, 59, 60, 61
Pleurodeles waltlii (Spanish ribbed newt) 4, 28, 50, 51, 60
Salamandra maculosa 63
S. salamandra (fire salamander) 19, 23, 35, 51, 60, 62
Taricha sp. (California or Western newt) 8, 16, 42, 59
T. granulosa (rough-skinned newt) 51
T. rivularis (red-bellied newt) 51
T. torosa (Western newt) 51
Triturus sp. 48
T. alpestris (alpine newt) 23, 35, 51, 60, 63
T. cristatus (crested newt) 18, 23, 50, 51, 60, 62, 63
T. helveticus (palmate newt) 23, 35, 50, 51
T. italicus 18
T. marmoratus (marbled newt) 35, 50, 51, 60
T. palmatus 63
T. vulgaris (common or smooth newt) 18, 23, 51, 60, 63

SIRENIDAE

Pseudobranchus striatuss (mud or dwarf siren) 5, 51
Siren sp. 48, 59
S. intermedia (lesser siren) 51
S. lacertina (greater siren) 5, 51, 60

Location of Suppliers

Bombina orientalis - fire bellied toad
Triprion petasatus - casque headed treefrogs
Agalychnis callidryas - red eyed tree frog
Rana pipiens (albino) - leopard frog
Megophrys nasuta - Asian horned frog
Atelopus varius - poison arrow frog
Eleutherodactylus inopatus - Haitian forest frog
Phrynohyas venulosa - marbled tree frog
Smilisca baudini - Central American tree frog
Pyxicephalus delalandei - puddle frog
Pyxicephalus adspersus - African bullfrog
Bufo alvarius - Colorado River toad
Xenopus laevis (albino) - African clawed frog
Hyla gratiosa - barking tree frog
Hyla versicolor - gray tree frog
Hyla septentrionalis - Cuban tree frog
Bufo cognatus - Great Plains Toad
Bufo speciosus - Texas toad
Scaphiopus hammondi - western spadefoot
Pleurodeles waltl - ribbed newt
Salamandra s. terrestris - European salamander
Typhlonectes natans - aquatic caecilian
Dermophis mexicanus - Central American caecilian

Herpetological Husbandry

Record Crocodile Growth Rate?

A marsh crocodile or mugger (Crocodylus palustris) reared from the egg stage at the Madras Crocodile Bank has grown at an unprecedented rate. This crocodile and 12 siblings hatched in May 1975 from eggs collected at Hogenakal, Salem District by Madras Crocodile Bank staff with Forest Department permission. All of the "Hogenakal hatchlings" have grown at a more rapid rate than the other 200 crocodiles at the Bank, but one particular animal (called M-2) outdoes them all (photograph). At hatching, M-2 was 28 cm in length and weighed 50 gms. In the first year he grew to 1.04 m and weighed 5 kg. By his second year he was 1.60 m and 12 kg. This year in June, M-2 was 3 years old and measures 2.10 m and 35 kg. He eats an average of 3 kgs of mixed fish per week. The average crocodile growth rate is said to be 30 cm per year. M-2 has averaged 60 cm per year but shows signs of slowing down.

Allen Vaughan, Crocodile Bank Manager, holding M-2, the 3 year old "Hogenakal Hatchling".

Black Pine Snakes Hatch at Philadelphia Zoo

Two adult pair of black pine snakes (Pituophis melanoleucus lodingi) are maintained at the Philadelphia Zoo. The breeding male arrived on 26 April 1973; the females on 14 May 1974 and 19 April 1977.

All four specimens were kept at 14.4° C throughout the winter; the temperature was elevated to 26.7° C in early April. Mating occurred shortly thereafter, with one male being responsible for both breedings. The second female laid a clutch of six eggs on 8 June, and the original female 5 eggs on 24 June. The eggs were incubated in moist beach sand at 26.7° C. One specimen hatched from the first clutch, and four from the second. The incubation period for both clutches was 65 days. The hatchlings are feeding on two-week old mice. We would appreciate hearing from anyone else who has successfully reproduced this subspecies.

New Reptile Display at Cohanzick Zoo

The Cohanzick Zoological Society has begun construction of the new reptile display. This exhibit will be approximately 10' long, 5' wide and 4' high. It will include Jersey stone, pools and natural paintings relevant to South Jersey. The zoo is working closely with the state of New Jersey Fish and Game Department to furnish reptiles native to this area. The display will be open for public viewing by January 1979.

Floating Containers for Rearing Tadpoles

Large tanks of various designs have been used successfully in rearing anuran tadpoles. Designs or descriptions of some rearing tanks are available in the literature (see Stenroos, 1978), and other rearing tanks are available commercially (e.g., "Min-O-Cool" and "Living Stream" by Frigid Units, Inc., Toledo, Ohio). When using such tanks, I have found it convenient to also use several porous, floating containers to separate groups of tadpoles. In this way, the tadpoles can be reared in essentially the same chemical and thermal environment, but groups (such as the offspring of different matings) can be separated. The tadpoles are also easier to feed and capture when held in the smaller, floating containers.

Containers can be made from plastic boxes which are sold in department stores for storage of shoes or clothing. The two most commonly available sizes are 17 x 31 x 9 cm and 26 x 35 x 11 cm. I make the containers porous by punching holes, 1-2 cm apart, in all sides and bottoms of the boxes. The diameters of the holes depend on the species to be reared. Holes need to be small enough that early swimming larvae cannot escape, but large enough that fecal wastes are flushed out by the water circulating through the tank. Holes made by heating a standard dissection probe (1.2 mm diam.) and pushing it through the thin plastic walls are satisfactory for rearing both Pseudacris triseriata and Xenopus laevis tadpoles.

The containers are modified to float at the surface by gluing 2 x 2 cm strips of styrofoam around their outer rims, in the fashion of some commercial minnow pails. Some types of glue will dissolve the styrofoam, but 5-minute epoxy has worked well for me. The strips are glued flush with the rims of the plastic boxes, so they float with 2 cm "walls" above the surface. A completed floating container is shown in Fig. 1. Problems with tadpoles jumping these walls have not been encountered while rearing Pseudacris or Xenopus. For larger tadpoles, it might be necessary to use deeper styrofoam strips or to glue the strips lower down the sides to heighten the barriers separating tadpole groups, or to use the plastic covers which are supplied with the boxes.

I have not tested for optimum tadpole densities or crowding effects in any systematic fashion, but have had good success rearing both Pseudacris and Xenopus tadpoles by arbitrarily maintaining 25 tadpoles per 17 x 31 x 9 cm container or 50 tadpoles per 26 x 35 x 11 cm container. Tadpole densities will have to be adjusted through experience, and will be influenced by such factors as the total volume of the tank, the filtering efficiency of the tank, the frequency of water changes, the water temperature, and the size of the tadpoles.

Book Reviews

COMMON INDIAN SNAKES: A FIELD GUIDE by Romulus Whitaker. 1978. The Macmillan Company of India Limited, Delhi xiv + 154 p. 12.00 Rs (about $1.50 in India).

In the author's words "this book does not attempt to describe all Indian snakes,"...but presents "30 representative forms, most of which might be encountered by the average citizen." The goal of this volume is to provide a simple means of identifying Indian snakes and to characterize their ecology and habits. The writer's style is semi-technical, pleasant, and sometimes "off the cuff." The first half of the book is devoted to capsulized accounts of the "30 representative forms." Each contains information on the features, distribution, habits, food, habitat, status and other pertinent natural history. All 30 forms are illustrated with black and white photographs, most of which are acceptable to good in quality. Some of the species seldom photographed include: Perrotet's shieldtail, Plectrurus perroteti; banded kukri, Oligodon arnenensis; striped keelback, Amphiesma stolata; green keelback, Macropisthodon plumbicolor; olive keelback watersnake, Atretium schistosum; trinket snake, Elaphe helena; banded racer, Argyrogena fasciolatus; bronzeback tree snake, Dendrelaphis tristis; and, the slender coral snake, Callophis melanurus.

The book is interlaced with interesting natural history and "current status" tidbits. Excerpts include: "...rampant deforestation may lead to the extinction of some of the worm snakes (Typhlopidae) and Shieldtails (Uropeltidae)" "...Typhlina bramina exists in all female populations..." "Red sand boas Eryx johnii are one of the few snakes which can penetrate the blocked burrows of the rice destroying mole rat..." "Olive keelbacks eat mosquito larvae..." "Bronzebacks have no fear of falling and regularly jump among branches and to the ground from heights of 10-20 m..." "Vine nakes, Ahaetulla nasutus during the breeding season often bunch together in a cluster..." "Russell's vipers form a major resource of the skin industry in South India, and in some areas have been completely exterminated."

The remainder of the book is devoted to "General facts about snakes" including conservation and snakebite, a checklist of the snakes of India, and a key to Indian snakes which is adapted from Minton's (1962 AMNH Novitate No. 2081, p. 1-60) publication of Sind and Las Bela, West Pakistan. This portion of the book varies greatly in style and

treatment. The reader may be amazed how closely some of the "wives tales" of the region parallel ours, yet how bizarre are others. I was impressed by the real importance of snakes within many of India's subcultures and the size of the snakeskin industry. Between April 1967 and March 1968, India exported 358,413 kg of snake skins valued at 107,651,889.00 Rs. This in spite of the estimate by Dr. Salim Ali that "20-50 percent of India's grain crop is destroyed by rodents."

One of the most pleasant features of the book is the checklist of 233 species of Indian snakes, complete with English names and ranges. There are some questionable statements and a few typographical errors; however, the book is a must for anyone even vaguely interested in Asiatic ophidians. Mr. Whitaker is to be commended for providing impetus to our understanding of Indian herpetology and wildlife.

A FIELD GUIDE TO AUSTRALIAN FROGS by John Barker and Gordon Grigg. 1977. Rigby Limited, Sydney, 229 pp., cloth bound. (Obtainable from Dr. Gordon Grigg, Department of Biological Sciences, University of Sydney, Sydney, N.S.W., 2006, Australia, for $26.00 U.S. including airmail postage; make checks payable to Gordon Grigg).

The diverse and distinctive frog fauna of the Australo-Papuan Region has been the subject of more popular accounts in the last three years than ever before. Menzies' (1975) account of New Guinean frogs, Cogger's (1975) guide to Australian amphibians and reptiles, and Tyler's (1976) discourse on the biology of frogs all contain valuable information for the amateur and professional alike, and each is enhanced with excellent colored photographs of frogs. To the assemblage of distinguished books, another has been added.

Barker and Grigg's "Field Guide to Australian Frogs" is an attractive book printed on high-quality glossy paper, 135 x 180 cm and sturdily bound in green cloth. The colored photographs, depicting all species recognized prior to 1976, are superb. Almost all of the photographs, taken of frogs in natural settings, are the excellent work of Gordon Grigg. The color reproduction is generally excellent.

Although the book is designed as a field guide, three chapters deal with general topics. Chapter 1 is devoted to the evolution, taxonomy, and zoogeography of frogs. Here there are some minor errors concerning distributions of caecilians and salamanders, use of Protobatrachus for Triadobatrachus, and the specific statement: "As yet, no fossil frogs have been discovered in Australia..." Tyler (1974) reported fossil frogs from the mid-Miocene of Central Australia. Chapter 2, "Biology of Frogs," briefly treats locomotion, skin, senses, feeding and digestion, respiration and circulation, predation and defense, temperature relations, reproduction, and water relations. Despite the brief general treatment of these subjects, errors are few. On page 24, it is implied that all tadpoles are grazers, and the photograph on page 29 clearly shows ovulated eggs, not eggs contained in distended oviducts as stated in the legend. Chapter 4 deals with collecting, keeping and photographing frogs. The authors state that frogs are not protected by law except in national parks; presently frogs are protected in the Northern Territory, Victoria, and Western Australia. In the discussion of preserving frogs, no mention is made of the desirability of positioning the specimens in fixative. The method of obtaining excellent photographs of frogs is described.

The major part of the book is Chapter 3 on the systematics of the Australian frogs (170 pages). In this chapter, each family and genus is introduced, and each species is discussed with respect to identification, habitat, mating call, breeding and larvae, and similar species. Accompanying each species account is a colored photograph and an outline map of Australia showing the range in black.

I had an opportunity to use the book as a field guide in New South Wales and Queensland early in 1978. I found the descriptions to be reasonably accurate and the photographs to be tremendously helpful in identifying frogs. However, some errors were noted. On page 69, the top photo is Litoria inermis (not L. verreauxi) and the bottom photo is L. nigrofrenata (not L. jervisiensis). These photographs have been switched with those appearing on page 77, which in fact are L. verreauxi and L. jervisiensis (not L. inermis and L. nigrofrenata as labelled). The distribution maps are correctly identified. On page 83, the lower photograph is Litoria cyclorhynchus, not L. moorei, which is the top photograph on page 85.

Keys to the identification of frogs are notoriously difficult to construct and to use, especially those designed for nonprofessionals. Barker and Grigg have been fairly successful with their keys. Families are distinguished by brief diagnostic statements (pp. 40-41), but difficulty is evident in the Microhylidae, characterized by "... broad discs on the tips of the digits." This is not true for Spheno-phryne and several species of Cophixalus in Australia. In the key to Litoria (pp. 45-47), couplet 1b should go to 22, not 23; in couplet 11a, the posterior of thigh should be purple or orange; in couplet 22b, the dorsum should be green or brown. The inclusion of osteological characters in the keys of leptodactylid and microhylid frogs does not enhance the usefulness of the guide by amateurs. In place of a key to the complex of small frogs recognized in the genera Crinia, Geocrinia, and Ranidella, the authors present a lengthy table (pp. 180-183) summarizing morphological, reproductive, and distributional attributes of the 18 species.

Throughout the systematic accounts there are numerous errors. As examples: The account of the history of the name Nyctimystes on page 42 is completely incorrect (see Duellman and Trueb, 1976). In the discussion of the range of Limnodynastes (p. 104), Tasmania is omitted (inhabited by L. tasmaniensis), and New Guinea is not included in the range of L. ornatus. The meaning of the specific name of Limnodynastes terraereginae (p. 106) is Queensland, not "King of the Earth." The range of Rheobatrachus silus is not restricted to a single stream (p. 194); the species is known from three streams in the Conondale and Blackall ranges in southeastern Queensland; furthermore, the authors misquoted Corben, Ingram, and Tyler (1974) regarding the life history of Rheobatrachus. In their discussion of the Ranidae (p. 204), the authors used the generic name Gigantorana for Conraua.

Some of the maps are erroneous or difficult to interpret. The maps for Limnodynastes dumerilii (p. 109) and Neobatrachus pictus (p. 136) do not include the type localities. The restricted ranges of Pseudophryne australis and corroboree (p. 170) should have been emphasized by arrows. Taudactylus diurnus is consistently misspelled as "diurnis."

Despite some minor errors, Barker and Grigg's field guide is a great asset to biologists and naturalists interested in Australian frogs. In consort with Tyler's "Frogs" (Duellman, 1977), Australian naturalists now have two useful and complementary works on the anuran fauna. That fauna is still incompletely known; it is anticipated that the present field guide will be a great stimulus for additional studies of Australian frogs.

COMMENTARY ON TAXONOMIC PRACTICE IN REGIONAL HERPETOLOGICAL PUBLICATIONS: A REVIEW OF A PRELIMINARY ACCOUNT OF THE RATTLESNAKES WITH THE DESCRIPTION OF FOUR NEW SUBSPECIES by Herbert S. Harris, Jr. and Robert S. Simmons (1978. Bull. Maryland Herpetol. Soc., 14(3): 105-211), with comments on other Harris and Simmons rattlesnake papers.

It is unusual for articles appearing in serial publications to be reviewed; however, the incorrect and improper taxonomic practices utilized, the dubious ethical standards observed, the presumptuous attitude indicated, and the apparent lack of proper review process evinced, as well as a plethora of more minor errors included in the papers under review, make the writing of this review mandatory.

Our principal concern herein is to review the paper recently published by Herbert Harris and Robert Simmons in the Bulletin of the Maryland Herpetological Society (Vol. 14, No. 3, pp. 105-211) entitled "A preliminary account of the rattlesnakes with the description of four new subspecies." It is necessary, however, in so doing to comment as well on several other papers on rattlesnakes published by Harris and Simmons in recent years. Unless otherwise specified, our use of the phrase "Harris and Simmons" refers to the above-cited paper.

Harris and Simmons purport to have presented a "preliminary account of the rattlesnakes." In reality, they have presented only an abbreviated checklist in which they list all species and subspecies they recognize as valid (with incomplete synonymies) and include the "descriptions" of four new subspecies. In addition, they include photographs or drawings of all species and subspecies (a few of which have not been illustrated previously) and distribution maps for each.

Harris and Simmons stated (p. 105) that "two recently described subspecies on which the descriptions are in press are included as they should appear prior to this paper." Unfortunately, one of the papers in which one of the descriptions is included did not appear prior to the publication of the Harris and Simmons paper and the other did not appear prior to the submission of the Harris and Simmons paper for publication. They have committed, therefore, an act of heteroplagiarism and indicated the intent to commit an act of homoplagiarism (in the sense used by Smith, et al., 1975).

First we wish to discuss the case of heteroplagiarism. On page 111 of the Harris and Simmons paper they use the name Crotalus durissus neoleonensis for a subspecies of the Neotropical Rattlesnake from the Mexican state of Nuevo Leon in advance of the publication of a paper by Jordi J. Zertuche describing this subspecies. In addition, they furnish a photograph and provide a specimen number and a type locality for the holotype. In so doing, they have created a nomen nudum. Such names, fortunately, have no nomenclatural standing and, thus, once the Zertuche description is published, the name will be occupied as of that paper. It should be pointed out, however, that there is no need to, nor, indeed, is there any excuse for using a scientific name in advance of its formal description. This practice is unethical and contrary to the accepted rules of taxonomic procedure. Zertuche may well have reason to ask what right Harris and Simmons had to use his name in advance of its publication by him. We wonder why they could not have simply placed this taxon, unnamed, in proper sequence as they did with other undescribed taxa (e.g., Crotalus triseriatus subsp., Sistrurus ravus subsp.).

On page 112 Harris and Simmons used the name Crotalus durissus trigonicus for a subspecies of the Neotropical Rattlesnake occurring in the Rupununi Savanna in Guyana in advance of the known publication of the paper by the same two authors describing this subspecies. The paper describing C. d. trigonicus (Harris and Simmons, 1978) was accepted for publication on 13 April 1977 and the paper under review was supposedly submitted for publication (by Harris, the author, to Harris, the editor) on 6 November 1977. It is an extremely unwise procedure to use a name prior to its publication. With respect to the case in point, the issue of the Memorias do Instituto Butantan in which the description of C. d. trigonicus appears and which is dated 1976/1977 has yet to be accessioned into the collections of at least two university subscribers as of this writing. In fact, the issues of the Memorias do Instituto Butantan have a history of appearing at least a year later than the publication date printed on the issue. Harris and Simmons have demonstrated, therefore, the intent to commit an act of homoplagiarism (in the sense of Smith, et al., 1975) and to create a nomen nudum.*

These authors committed a similar error when in 1974 they used the name Crotalus willardi obscurus in a popularized article published in National Parks and Conservation Magazine, which also contained a photograph of a paratype of the subspecies, as well as an oblique reference to the distinctive characteristics of the taxon. Apparently, the action of including these extremely brief remarks was sufficient to occupy the name C. w. obscurus, according to Smith, et al. (1975). In the 1974 paper Harris and Simmons committed an act of homoplagiarism but avoided creating a nomen nudum because of the inclusion of the above-mentioned descriptive statements. A complete description followed two years later (Harris and Simmons, 1976). As we have pointed out above, a scientific name should never be used in advance of its known formal description. The rules of zoological nomenclature have been established so as to allow for the stabilization of scientific names. Subversion or ignorance of these rules cannot be condoned.

On another matter, Harris and Simmons presented "abbreviated descriptions" of four new subspecies of rattlesnakes (Sistrurus ravus brunneus, S. r. lutescens, Crotalus ruber monserratensis, and C. triseriatus quadrangularis) in advance of the "formal descriptions" they are intended to follow. Harris and Simmons stated that "although this is not a standard practice, we hope it will be tolerated for the sake of

*Information recently received from the Chief Librarian at the Instituto Butantan concerning the dates of publication and distribution of the volume of the Memorias do Instituto Butantan in which the above-discussed paper was published, indicates that volume 40/41 (1976/1977) was published in September of 1978 and distributed on November 22, 1978. The issue of the Bulletin of the Maryland Herpetological Society in which the above reviewed Harris and Simmons paper was published and in which the name C. d. trigonicus is used is dated September, 1978 and was received by one of us (JRM) on 6 November 1978. Harris and Simmons, therefore, actually did commit homoplagiarism.

completeness." They are entirely correct in stating that this is not "standard practice." On the one hand, this practice is by no means taxonomically defensible and cannot be "tolerated" for the sake of completeness or any other reason. There is no reason whatsoever that these "abbreviated descriptions" should ever be published in advance of the complete description. We now wish to discuss the problems that can thereby arise.

Harris and Simmons described a new subspecies of Crotalus triseriatus from Hidalgo. In the vague diagnosis of this new subspecies, C. t. quadrangularis, they compare it almost exclusively to C. aquilus, which they raised to specific rank in this paper (it was formerly considered a subspecies of C. triseriatus). They only briefly compare C. t. quadrangularis to C. t. triseriatus and not at all to C. t. anahuacus, which latter subspecies Harris and Simmons resurrected in this paper. In addition, the statement that compares C. t. quadrangularis to C. t. triseriatus is inexplicable to us, inasmuch as they say that "C. t. quadrangularis can be separated from C. t. triseriatus in having a larger rattle size as was indicated by Klauber for C. aquilus." A diagnosis of a new subspecies should ideally compare the new taxon to all previously described subspecies within the species, but should certainly not compare the new subspecies almost exclusively to another species!

Another "abbreviated description" needs to be examined critically. On page 122, Harris and Simmons described Crotalus ruber monserratensis. The "diagnosis" they present is extremely vague, using phrases such as "smaller head," "higher number of body blotches," and "lower number of subcaudals," none of which, of course, will serve to distinguish C. r. monserratensis from any other subspecies within the species. In this instance, Harris and Simmons have occupied the name C. r. monserratensis but have presented a diagnosis so vague that they have, in fact, produced a nomen dubium.

The other two "abbreviated descriptions" of new subspecies (those of Sistrurus ravus brunneus and S. r. lutescens) are similarly poorly executed and will be discussed in a revision of this species by Jonathan Campbell.

Several comments are necessitated concerning the resurrection by Harris and Simmons of three subspecific names in the genus Crotalus. First of all, they resurrect C. horridus atricaudatus from the synonymy of the species but provide no rationale for doing so, while citing in their synonymy of this taxon the paper by Pisani, Collins, and Edwards (1973) which substantiated the relegation of the name atricaudatus to the synonymy of the nominate (and only other) subspecies.

A similar situation involved the resurrection of C. ruber elegans from the synonymy of C. r. ruber. Harris and Simmons again used vague statements to substantiate their position. They stated that "these snakes (C. r. elegans) are stunted as compared to C. r. ruber from the mainland and differ in some meristic characters." They also indicated that "these differences will be treated at length in a future paper." We are of the opinion that there is no reason whatsoever that the resurrection of C. r. elegans should have been mentioned in the paper under review. It is not therein substantiated and the matter should have been left to be treated in the "future paper."

The rationale for the resurrection of C. triseriatus anahuacus is similarly vague. They stated that members of this subspecies are "dark" and have "the blotches reduced to spots." One would have to be intimately familiar with Crotalus triseriatus to understand what their statements mean. It is our strong opinion that no taxon should be resurrected without an adequate substantiation of the reasons for so doing.

Harris and Simmons also elevated Crotalus aquilus to specific status. In doing so they stated that they may be opening a "can of worms." We agree, inasmuch as nowhere in their paper can we find any justification for this taxonomic change. The question of the relationship of Crotalus aquilus to C. triseriatus is still very much unanswered. In addition, we wish to point out that Harris and Simmons' statement (p. 105) about the "paratypic series" of Crotalus aquilus containing three species, C. pricei, C. triseriatus, and C. aquilus, is misleading. Klauber (1952) designated only a holotype for C. aquilus. In addition, he also listed a series of 41 specimens as a topotypic series and had at his disposal other specimens from other areas of the range. It appears that Harris and Simmons have confused the meaning of the terms topotype, paratype, and hypodigm.

Another matter of concern with respect to this paper, as well as another paper by Harris and Simmons, is their designation of material in their joint private collection as type specimens. The holotypes of both Crotalus ruber monserratensis and C. triseriatus quadrangularis are specimens in the Harris-Simmons private collection. We consider this to be a very inadvisable procedure which should be discontinued. Type material of any taxon ought to be placed in a permanent museum collection, given the notorious impermanence and/or inaccessibility of private collections (a case in point - the E. Ross Allen-Wilfred T. Neil collection from Belize). They followed the same procedure in another recently published paper (Harris and Simmons, 1978), wherein they described C. durissus trigonicus and named as holotype a specimen in their private collection. We would like to suggest that it would be appropriate for Harris and Simmons to deposit the type material in their private collection in a permanent collection and to use the pages of the Bulletin of the Maryland Herpetological Society to publish the new numbers.

The case of C. durissus trigonicus is especially interesting inasmuch as they chose to designate as holotype a specimen in a private collection with vague locality data and no collector's name, whereas they cite as paratypes specimens in the Florida State Museum collections with precise locality data and collectors' names available (Allen and Neill, 1957). Inasmuch as the data accompanying this holotype is very vague, we wonder if the specimens were purchased from an animal dealer and, if so, why was it designated as holotype when museum material was available? Furthermore, the diagnosis of C. d. trigonicus is poorly drawn. They use two characters of pattern (plus the stunted size) to diagnose this subspecies. One character, that of the pale triangular mark on the supraoculars, is shared with some specimens of C. d. dryinus. The other character, that of the white-tipped scales bordering the dorsal rhombs, is not faithfully translated from the information on color in life provided by Allen and Neill (1957). The latter authors stated that the dorsal rhombs are "bordered by yellow- or white-tipped scales" (underline ours). Allen and Neill (1975) provided a good description of the stunted savanna form but chose not to name it. Harris and Simmons, with scant more information (that provided by the holotype discussed above) than that available to Allen and Neill, chose to do so, using vague and non-discriminatory characters, while acknowledging that a "final" appraisal of the species is not yet available. We would like to suggest that improvement in our knowledge of the systematics of Crotalus durissus will not come from continued descriptions as subspecies of material from isolated populations, but rather will come from a study of the available material from the length of the range.

On page 135 of the "preliminary account of the rattlesnakes" they describe a new subspecies of Sistrurus ravus, S. r. brunneus, from central Oaxaca. Their photograph (their fig. 87) of "S. r. brunneus,"

however, is of a specimen from "near Huajuapan, Oaxaca," which locality lies within the range of the nominate subspecies (as evidenced by their map 31). Such carelessness is inexcusable, inasmuch as the photograph is part of the description of a new taxon. In addition, we wonder upon what basis Harris and Simmons mapped the range of a subspecies (S. ravus subsp. from Guerrero) being described by someone else?

Some minor errors require discussion, most of whch are indicative of the lack of proper review process. We are dubious about the value of reprinting the abbreviated synonymies provided by Harris and Simmons, information already available elsewhere (in the 1956 and 1972 editions of Klauber's rattlesnake monograph), but if they wish to do so, they ought to transcribe the information correctly. A case in point is the synonymy they provide for Crotalus viridis concolor. Either they should have cited Klauber's 1930 description of Crotalus confluentus decolor, an important component of the synonymy of C. v. concolor, or have made the synonymy consistent with that used for most of the other taxa listed.

In an editor's note on the contents page of the issue of the Bulletin of the Maryland Herpetological Society containing Harris and Simmons' "preliminary account of the rattlesnakes," the editor (Harris) mentioned two specimens of Crotalus tigris from Isla Tiburon, Gulf of California, which constitute a new insular record for the species. The specimens were collected during the period of September-October 1976. Harris cited the numbers of the specimens as USNM 093591 and 093692. These numbers are not permanent museum numbers, but are rather field numbers, inasmuch as the USNM permanent numbers at that time were over 150,000, and their proper status should have been so stated.

In so little prose as is present in Harris and Simmons' "preliminary account of the rattlesnakes," one would expect a greater degree of attention to syntax. For example, what is a "nominate species" (p. 105)? Also, they stated that "this snake (Crotalus aquilus) is intermediate in many characters between C. triseriatus and C. lepidus, but is as different (from what?) as they are from each other." And again, C. triseriatus anahuacus "describes the high elevation montane form occurring on all the peaks across the Volcanic Axis of Mexico (in) being dark...." "At this time, the list reflects our current understanding..." is redundant. The second "sentence" of the Acknowledgments section is incomplete. Latin is a proper noun (p. 211, paragraph 3). The statement "Angela Czarnowsky deserves credit for her many drafts of this manuscript" suggests that Angela, not Harris and Simmons, wrote the paper under review. And finally, the statement "Geneva Ambrose and my daughter, Karin Sue Harris also deserve thanks for the many long hours spent away in connection with this paper" suggests that the two ladies were either sent away or stayed away voluntarily so that Harris and Simmons could write the paper. Incidentally, in a coauthored paper "my daughter" should be "the daughter of the senior author" or something similar. This last comment, as well as similar references to "my measurements" (p. 308) and "I would like to thank" (p. 310) in the paper describing C. durissus trigonicus raises the question as to which of the authors, Harris or Simmons, actually wrote these papers.

The "preliminary account of the rattlesnakes" occupies 106 pages of issue number 3 of volume 14 of the Bulletin of the Maryland Herpetological Society, but, in fact, provides very little information not already available elsewhere. The bulk of the paper consists of abbreviated synonymies, photographs, and distribution maps of the rattlesnake taxa, most of which information is in Klauber's (1972) rattlesnake monograph. For example, each species' distribution is mapped, but the maps are primarily copies of Klauber's (1972) maps. In addition, each species is mapped separately, occupying thereby far more space than is warranted by their value. Harris and Simmons have used 31 maps to convey essentially the same information Klauber provided in 10 maps. We also wonder if the University of California Press might not have a legitimate complaint concerning this extensive use of copyrighted material. The same remark regarding the lack of new information might be directed toward two other Harris and Simmons offerings. In 1972, they published two papers on Crotalus durissus, which also contain almost no new information and are taken essentially from Hoge (1966) and Peters and Orejas-Miranda (1970). In the key (1972b) they stated that the characters given by Peters and Orejas-Miranda (1970) are difficult to use in practice, then proceed to use basically the same characters, only slightly rearranged.

We are concerned about the apparently presumptuous attitude evinced by Harris and Simmons toward other previous students of rattlesnakes. The main paper herein under review is entitled "A preliminary account of the rattlesnakes...." One is left to wonder what status is accorded to Howard Gloyd (1940) and Laurence Klauber's (esp. 1956, 1972) monumental works on this group. In another instance, Harris and Simmons (1977) purport to have presented "a preliminary account of insular rattlesnake populations, with special reference to those occurring in the Gulf of California and off the Pacific coast." This can hardly be considered a preliminary work, however, inasmuch as our modern knowledge of the distribution of insular rattlesnakes dates back to at least as far as Schmidt (1922). Since that time, several other authors have summarized information regarding the distribution of rattlesnakes on the islands of the Gulf of California (e.g., Cliff, 1954; Soule and Sloan, 1966) or both those of the Gulf islands and those on the Pacific side of the peninsula of Baja California (Klauber, 1972). In addition, this Harris and Simmons paper of 19 pages provides little new information. In fact, they cite only two insular records that were not previously cited in papers by Cliff (1954), Soule and Sloan (1966), Hardy and McDiarmid (1969), and Klauber (1972). Finally, in their description of C. durissus trigonicus they stated that "Klauber (1972) in his revised edition of the 'Rattlesnakes' did not apparently understand Hoge's (1966) work, and did not recognize his revision of the South American C. durissus." In point of fact, Klauber (1972), in an extensive footnote (p. 35), presented his reasons for not including Hoge's taxonomic changes within Crotalus durissus in stating that "it appears to me that Hoge's work is not sufficiently complete and detailed to permit the segregation and differentiation of these 8 subspecies and therefore I have not deemed it advisable to give them full recognition and acceptance for inclusion in the list of species contained in Chapter 1, or in the checklist, synonymies, maps, and keys contained in Chapter 2." We agree entirely with Klauber's (1972) assessment of Hoge's (1966) work and, furthermore, consider Harris and Simmons' statement quoted above to constitute an affront to the memory of a herpetologist whose stature in the history of not only the study of rattlesnake biology, but of the herpetology of the western United States and Mexico as a whole, is unquestionable. Along these same lines, the statement that Harris and Simmons "are currently evaluating the taxonomy and distributions of all rattlesnake species using all available taxonomic techniques" (underlines ours) is similarly presumptive. Certainly the work they have produced to date on rattlesnakes would not indicate that they are using all available taxonomic techniques. The implication of the statements quoted above is that Klauber, at his death, left the taxonomy of rattlesnakes in such a sorry state that there is a need on

Harris and Simmons' part for a comprehensive study of the taxonomy of the rattlesnakes, which is simply not the case.

It is obvious that the major paper herein under review did not go through a proper review process prior to its publication. We cannot believe that the taxonomic and nomenclatural errors committed or the various unprofessional statements included would have ever survived review by a herpetologist. Furthermore, in view of the amount of duplicated information included, it is extremely unlikely that the paper, in its present form, would have ever seen the light of day in any other than a journal essentially under the editorial control of one of the authors. Placing a date received and a date accepted at the end of the paper was a nice touch and thereby implicates one or all of the four herpetologists listed on the contents page as reviewers for volume 14 as having reviewed this paper, but we doubt very much that the manuscript ever left Harris and/or Simmons' desk.

We feel that we have raised some points of considerable concern with respect to the role of regional herpetological publications in systematic herpetology. We offer the following suggestions that can serve as guidelines not only for the Bulletin of the Maryland Herpetological Society but for regional journals in general, viz:

1. Descriptions of new taxa should not be published in regional herpetological journals but should be submitted to journals with a national and/or international scope, wherein they can be subjected to proper peer review and maintained for posterity.

2. A peer review process should be instituted for all taxonomic papers submitted to regional herpetological journals, including submission of papers for review to at least one recognized authority not directly connected to the journal in question.

3. By all means, the internationally accepted rules of zoological nomenclature as printed in the International Code of Zoological Nomenclature should be followed, regardless of the nature of the paper being published.

We have undertaken this review in the hopes that the kind of errors discussed above will be avoided in the future.

Regional Society News

The Australasian Affiliation of Herpetological Societies

The Affiliation was formally established in 1977 to encourage the scientific study of amphibians and reptiles, and their habitats, to publish the journal Herpetofauna, to promote liaison between the member societies through conventions, publications and field work, and to represent the interests of its member societies.

It is a non-profit organization with the prime executive purpose of pooling the publishing resources of herpetological societies in the Australasian Region. Five societies have to date joined the Affiliation (four in Australia and one in New Zealand); there are two other herpetological societies in the Region and they have been invited to participate.

PUBLICATIONS

Member societies bulk subscribe to Herpetofauna on behalf of their members, and it is posted out direct. Overseas and Australasian herpetologists who do not belong to one of the affiliated societies can subscribe direct to the Affiliation. An Australasian herp keepers manual is in preparation and other special Regional publications are planned.

CONVENTIONS

In April 1978, the first very successful four day convention was held at Wilcannia in far western New South Wales. Sixteen delegates attended from Adelaide, Melbourne and Sydney; the seminar sessions and field work were most productive. Many common problems were resolved and a fruitful exchange of ideas occurred.

The next convention will be at Whyalla in South Australia during March 1979.

INVITATION

Overseas and Australasian herpetologists who do not now receive Herpetofauna are invited to subscribe directly to the Affiliation (use application below). Back issues are also available.

The Australian Society of Herpetologists

The Australian Society of Herpetologists is a scientific organization whose aims are to promote the study and conservation of amphibians and reptiles. Membership is open to professional scientists and scientifically-interested amateurs who are engaged in some aspect of herpetological research.

The Society publishes a Newsletter two to three times a year. The Newsletter contains news of members, lists of recent literature relevant to Australian herpetology, and other items of general herpetological interest. The Society also encourages dissemination of information among members by means of regular meetings, usually held in conjunction with the meetings of The Australian and New Zealand Association for the Advancement of Science.

Subscription to the Society is $A2.00 per annum (two Australian dollars). Overseas subscriptions should be in the form of a bank draft or cheque; personal cheques are not acceptable. The subscription covers membership dues and receipt of the Newsletter.

Application for membership, accompanied by a cheque for $A2.00 (International cheque please), should be forwarded to:

Margaret Davies, Secretary-Treasurer
Department of Zoology
University of Adelaide
North Terrace
Adelaide, South Australia

Legislative Alert

Animal Dealer Fined

A south Florida animal dealer has been fined $5,000 for selling four indigo snakes. John P. Anthony, Coral Gables, was arrested on the charge that he shipped the snakes to a Michigan address in violation of federal regulations.

The Eastern indigo snake, a favorite with collectors throughout the United States, is considered a threatened species.

Indigos are now found only in Florida and Georgia. Its range once included Alabama, Mississippi, and South Carolina, but there have been no confirmed sightings of the snake in these states since the 1950's.

Commercial trade by pet dealers is believed to be the main cause for the decline of the species. Eastern indigo snakes are extremely docile, colorful, and grow as long as eight feet, making them highly desirable as pets to snake fanciers. Prime specimens sell for as much as $250 in the Northwest.

...from Florida Wildlife, November-December 1978.

Alligator Smuggling Investigation Concluded

Jail sentences and fines totaling $87,500 for three men and three corporations have resulted from a major wildlife law enforcement case involving the illegal commercialization of more than 2,500 hides of Endangered American alligators (Alligator mississippiensis).

Jacques Klapisch was sentenced November 17th in the U.S. District Court, Eastern District of New York, to 4 months imprisonment and fined $10,000 on one count of conspiracy to violate the Lacey Act. Klapisch illegally purchased the skins in the Southeastern United States, transported them to New York, and shipped them to tanneries in Japan and France.

Meg Import Corporation was fined $39,000 on 12 counts of violating the Lacey Act by shipping hides out of the U.S. using false and fictitious documents. Collaborators Egawa International and Gunze, also New York import/export firms, were fined $12,500 and $21,000, respectively, for their involvement in the smuggling operation. William Greenblatt and Kiyoshi Egawa each received $2,500 fines, and John Kelley was sentenced to 4 months in jail.

The convictions resulted from investigations conducted by special agents of the U.S. Fish and Wildlife Service and U.S. Customs Service since 1974.

...from Endangered Species Tech. Bull., 3(2): 12(1978).

Proposition Herptile

The following excerpted from the Los Angeles Times, 23 Sept. 1977, Part II, Page 6:

California Governor Brown vetoed a bill to extend until 1980 permission to import meat from pen-reared green sea turtles from Grand Cayman Is. In doing so, Brown stated, "Green sea turtles make soup, steak, pretty shells and cosmetic oil. Once there were tens of millions, now there are only thousands making their mysterious voyage through the seas from nesting beaches to distant feeding grounds. Some say farming green sea turtles in captivity will bring them back. Others see such commercial ventures as just expanding the appetite for this threatened creature. I incline to the latter and believe what turtles need is less people taking their eggs and depleting their species."

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Standard Common and Current Scientific Names for North American Amphibians and Reptiles (Collins, Huheey, Knight and Smith, 1978). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Department of Biology, Virginia Commonwealth University, Richmond, Virginia 23284. Short manuscripts are only acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

CAUDATA

AMBYSTOMA ANNULATUM (Ringed Salamander). USA. OKLAHOMA: McCurtain Co., 2.4 km N Garvin (T7S, R23N, Sec. 6); 2 April 1977. R. Justice, S. Minter. Verified by S. Minter, R. W. VanDevender. Oklahoma St. Univ. Mus. OSUM A4963. Range extension of approximately 193 km S of specimen collected 14.5 km NE Sallisaw, Sequoyah Co., Oklahoma (Anderson, J. D., 1965. Cat. Amer. Amph. Rept., 191). Represents a McCurtain Co. record and a first record for the Gulf Coastal Plain.

Submitted by STEPHEN MINTER, Rt. 2, Box 27A, Stillwater, Oklahoma 74074. ●

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA. NORTH CAROLINA: Alleghany Co., approximately 5 km NW Cherry Lane: approximately 13 km south of Virginia border on the Blue Ridge Parkway. 30 March 1978. C. Erwin and T. Newcomb. Verified by E. E. Brown, Davidson College Bio. Dept. Private collection of E. E. Brown; will be donated to North Carolina St. Mus. Nat. Hist. Gravid female collected from bottom of shallow woodland pool; layed two egg masses in captivity on following night, a month later than any previously recorded breeding activity. First record for county and extends range 100 km NE of any previously recorded localities (Cooper, Robinson, and Funderburg, 1977, Endangered and Threatened Plants and Animals of North Carolina, N. C. State Museum of Natural History, Raleigh, pp. 318-19).

PLETHODON DORSALIS (Zigzag Salamander). USA. LOUISIANA: West Feliciana Par.: Tunica Hills Nature Preserve, 3.6 airline km W Weyanoke. 25 February 1978, 11 March 1978. A. J. Meier. Louisiana St. Univ. Mus. Zool., LSUMZ 35382-35383. First record from Louisiana. Extends range 322 airline km SW isolated Winston Co., Mississippi, record (Ferguson and Rhodes, 1958, Herpetologica 14: 129) and 322 airline km WSW isolated Clarke co., Alabama, record (Blaney and Relyea, 1967, Herpetologica 23: 246-247), both of which are in the Tombigbee River drainage. The Louisiana locality lies in the Bluffflands, a narrow band of deeply dissected, hardwood-covered loessial hills that forms the eastern border of the lower Mississippi Valley. The specimens were collected beneath relatively small logs on a natural terrace near the bottom of a deep ravine. The habitat is similar to that depicted by Blaney and Relyea (op. cit., Fig. 1).

SERPENTES

ERIDIPHAS SLEVINI. MEXICO: Baja California Sur: 12.2 km S (by Mexican hwy. 1) San Ignacio. 7 May 1978. R. L. Seib. Calif. Acad. Sci., No. 146499. Extends range 220 km NW Loreto, nearest recorded locality (Leviton and Tanner, 1960, Occ. Pap. Calif. Acad. Sci. No. 27). Contrary to Tanner (1966, Trans. San Diego Soc. Nat. Hist. 14: 189-196), Eridiphas does not require streamside habitats. The nearest permanent water to the above specimen is at San Ignacio. Another specimen, R. L. Sieb, Calif. Acad. Sci., No 146498, was found 28.8 km NW (by Mexican hwy. 1) Santa Rosalia, site of nearest permanent water to this specimen.

Submitted by ROBERT L. SEIB, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720. ●

THAMNOPHIS CYRTOPSIS CYRTOPSIS (Western Blackneck Garter Snake). USA. NEW MEXICO: Sierra Co: Ash Canyon, 1.25 km SSE Elephant Butte. 26 July 1978. A. H. Price. New Mexico St. Univ. collection, NMSU 5462. Conant (1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton-Mifflin, Boston) shows a hiatus for this subspecies in the Rio Grande valley from north of Albuquerque to the southern border of the state, apparently using the 5000 ft. contour level as the eastern and western distributional boundaries in the valley. Furthermore, a survey of 30 museums holding herpetological specimens from the area reported here (available from the U. S. Bureau of Land Management District Office, Las Cruces) reveals no specimens of this snake. The nearest published localities for this subspecies (Milstead, 1953, Texas J. Sci. 5(3): 348-79) are 66.7 km NW and 106.7 km NE of the one reported here. This specimen establishes the presence of T. c. cyrtopsis in the Rio Grande valley near the southern end of Elephant Butte Lake, 26.0 km west and 21.5 km east of the 5000 ft. contour level at an elevation of approximately 4300 ft.

Submitted by ANDREW H. PRICE, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. ●

HERPETOLOGICAL RECORDS FROM NORTHWESTERN OKLAHOMA

During the course of field studies since January 1971, numerous county and other distribution records have been accumulated from northwestern Oklahoma. The following records supplement Webb (1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Specimens are in the collection of the author (RLL) unless otherwise stated.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle). Ellis Co: 2.5 km N Fargo, 28 June 1975 (RLL uncatalogued). Garfield Co: Vance AFB housing area, Enid, 3 July 1971 (RLL 715). Kay Co: 10 km NW Braman, 6 Aug. 1976. L. Miller (RLL live). Logan Co: 12.2 km NW Mulhall, 23 May 1975 (RLL 1293). Chrysemys scripta elegans (Red-eared Slider). Ellis Co: 2.5 km N Fargo, 28 June 1975 (RLL live). Blaine Co: 2.4 km N Canton, Canton Lake dam, 9 June 1978 (RLL uncatalogued). Garfield Co: 4.5 km S Enid, 10 June 1971 (RLL 739). New Departmental Records for Reptiles and Amphibians From Honduras

During the course of field work in Honduras, principally dealing with a study of the dry forest herpetofauna in that country, we amassed material representing a considerable number of new departmental records. These records are reported below and supplement information supplied by Meyer and Wilson (1971, Los Angeles Co. Mus. Contrib. Sci., no. 218: 1-47; 1973, Los Angeles Co. Mus. Contrib. Sci., no. 244: 1-39), Hahn (1971, Herp. Rev., 3: 111-112), Hahn and Wilson (1976, Herp. Rev., 7: 179), Wilson, McCranie, and Porras (1978, Herp. Rev., 9: 63-64), Wilson, Myton, and Cruz (1976, Herp. Rev., 7: 179), and Wilson and Meyer (in press, The snakes of Honduras, Ralph Curtis Publications, Hollywood, Florida). All specimens are deposited in the Louisiana State University Museum of Zoology (LSUMZ).

Two Additions to the Reptile Fauna of Honduras, Eumeces managuae Dunn and Agkistrodon bilineatus (Gunther), with Comments on Pelamis platurus (Linnaeus)

Continuing work by the members of the Departamento de Biologia of the Universidad Nacional Autonoma de Honduras and the Direccion General de Recursos Naturales Renovables has demonstrated the presence of two additions to the known reptile fauna of Honduras. These additions, one a skink (Eumeces managuae) and the other a snake (Agkistrodon bilineatus), are discussed below. In addition, another locality is reported for Pelamis platurus, recently added to the herpetofauna of Honduras. All three specimens reported herein are deposited in the Museo de Flora y Fauna of the Universidad Nacional Autonoma de Honduras (UNAH).

Eumeces managuae Dunn

The range of the skink Eumeces managuae Dunn, 1933 was mapped by Duellman (1966), indicating a distribution encompassing a narrow strip into northwestern Costa Rica. The range also extends between lakes Managua and Nicaragua into a small area east of those lakes.

Prior to this report, the species was not known to occur in Honduras (Meyer and Wilson, 1973). In February 1977, a specimen of Eumeces managuae (UHAH 5521) was collected by Jonathan Espinosa in the yard of the Sea Farms Company in Punta Raton, a small town located on Bahia San Lorenzo, Golfo de Fonseca, Depto. Choluteca at an approximate elevation of two meters. The specimen was found under a pile of rocks in a disturbed area behind a house. This area falls within the Tropical Dry Forest formation of Holdridge (1967).

The Nicaraguan record most proximate is the airport at Managua (Jaime Villa, pers. comm.), the type locality of the species. The Honduran record represents a northward range extension of approximately 85 airline kilometers.

The Honduran specimen is a female with a total length of 245 mm (tail regenerated, but, apparently completely so) and a SVL of 95 mm. In scutellation, UNAH 5521 agrees well with the description given by Taylor (1956). There are 68 scales from parietals to above the vent, of which four are enlarged nuchals, and 17 scales around midbody.

The coloration in life may be described as follows: dorsal ground color yellowish-brown; two black paravertebral stripes beginning on the parietals and extending to the posterior limb insertion, thereafter continuing onto dorsum of tail, gradually breaking up into discrete spots; two dorsolateral stripes on each side beginning just above the ear opening and continuing to the posterior limb insertion, thereafter fusing, breaking into discrete spots, and continuing onto tail; venter immaculate white; each scale on top and sides of head with a well-defined black spot.

Agkistrodon bilineatus (Gunther)

The distribution of the cantil, Agkistrodon bilineatus (Gunther), 1863 is known to encompass the Pacific coast of Middle America from southern Sonora, Mexico to northwestern Costa Rica and the Caribbean coast in Neuvo Leon and Tamaulipas, Mexico and in the Yucatan Peninsula, including Belize (Bolanos and Montero, 1970; Burger and Robertson, 1951; Gloyd, 1972; Henderson and Hoevers, 1975). However, a recent study of the snake fauna of Honduras (Wilson and Meyer, in press) indicated that the species probably occurred in Honduras, but that no specimens had been collected.

A specimen of Agkistrodon bilineatus from Honduras (UNAH 5516) is now available. It was collected in May 1976 on the island of Zacate Grande in the department of Valle. This is the area in which the cantil has been expected to occur. The nearest records in Nicaragua and El Salvador are from ca. 16 km N Sebaco, Depto. Matagalpa (Jaime Villa, pers. comm.) and from near Sonsonate, Depto. Sonsonate (Mertens, 1952), respectively.

The Honduran specimen is a female with 130 ventrals and 45+ subcaudals (perhaps 1 to 3 subcaudals are missing from the end of the tail). The specimen is probably an adult, with a total length of 715+ mm and a tail length of 112+ mm. The lower pale line on the side of the head crosses the supralabials above the commissure and is narrowly bordered by dark pigment above and below. The upper pale line is thin and poorly developed. The ground color of the dorsum is tan, strongly contrasting with the grayish-brown crossbands. Only a few scattered white spots are present along the edges of the crossbands, mostly distributed along the lateral portions. There are 15 crossbands on the left side of the body. The venter is more-or-less uniform pale gray with few pale markings along the lateral portions of the ventral scales.

Gloyd (1972) provided characterizations of the three subspecies of A. bilineatus. Although the tail is incomplete, the extrapolated subcaudal number of 4 to 48 most closely resembles that of A. b. taylori (Gloyd, 1972, gave a count of 47 for 2 females). The count for the Honduran specimen falls below the range given for A. b. russeolus (49-61; Gloyd, 1972) and considerably below that for A. b. bilineatus (59-64; Gloyd and Conant, 1943). In the lower pale face stripe character, UNAH 5516 resembles either A. b. bilineatus or A. b. russeolus. In dorsal pattern, it resembles none of the described subspecies. Unlike A. b. bilineatus, the subspecies expected to occur in the area, this specimen has conspicuous pale interspaces between the dark dorsal crossbands, thus resembling either A. b. taylori or A. b. russeolus. However, unlike either of those two subspecies, UNAH 5516 has narrow, poorly-developed white markings along the edges of the dorsal crossbands. The ventral pattern most closely resembles that of A. b. bilineatus, as described by Gloyd (1972).

In summary, the Honduran specimen of Agkistrodon bilineatus resembles none of the described subspecies in pattern, and, in sum total, its diagnostic features do not ally it with A. b. bilineatus, the subspecies occurring along the Pacific coast of Mexico and Central America. Whether the pattern of this specimen is typical of the Honduran population or is aberrant is a question that will only be answered with the collection of additional material.

Pelamis platurus (Linnaeus)

Wilson, McCranie, and Porras (1978) recently reported the first specimens of the Yellow-bellied Sea Snake, Pelamis platurus (Linnaeus), 1766 from the territorial waters off the Pacific coast of Honduras. Those three specimens were found on the beach at Cedeno, Depto. Choluteca. This town lies on the shore of the southern arm of the Golfo de Fonseca.

In August, 1976 an additional specimen of P. platurus (UNAH 5518) was collected by Roberto Soto at the port of San Lorenzo, Depto. Valle, within the Bahia San Lorenzo, a bay located about midway between the upper and lower arms of the Gulf of Fonseca.

The two known localities for P. platurus in the Pacific coastal territorial waters of Honduras are approximately 25 airline kilometers apart and firmly demonstrate the occurrence of this sea snake in the Gulf of Fonseca. The regularity of their occurrence in these waters is questionable, however. Whereas the fishermen in the town of Cedeno with whom Wilson, McCranie, and Porras talked in the summer of 1976 were familiar with this snake, they com-

mented as well upon its rarity. The old fishermen in San Lorenzo, on the other hand, had never seen the animal.

News Notes

GOPHER TORTOISE COUNCIL

During the past several years, people in the southeastern United States have become alarmed over the decline of the gopher tortoise, Gopherus polyphemus. This concern has led to the formation of the Gopher Tortoise Council, a group having as its primary goal to assure the continued survival of viable populations of gopher tortoises throughout their natural range. At this time, the Gopher Tortoise Council is soliciting your support for the protection of this species by asking interested persons to join the council. For further information, please contact Richard Franz, Florida State Museum, University of Florida, Gainesville, Florida 32611.

ITTS JOURNAL NEEDED

Derek J. Foxwell is interested in purchasing a complete set (or individual issues) of the defunct International Turtle and Tortoise Society Journal. Anyone wishing to sell same should contact Mr. Foxwell at: Conservation Section, The City Museum, Queens Road, Bristol, B58, IRL, England.

A NEW HERP PUBLICATION

Behavior and Neurology of Lizards. Proceedings of an interdisciplinary conference sponsored by HEW's National Institute of Mental Health (NIMH) and the Smithsonian Institution's National Zoological Park. The 350-page volume was edited by Paul D. MacLean, Chief of the NIMH Laboratory of Brain Evolution and Behavior, and Neil Greenberg, of the Zoological Department of the University of Tennessee.

Contents of the volume are presented under three major headings: "Neurology," "Laboratory Studies of Behavior," and "Field Studies of Behavior." Eighteen scientific papers are included, and a summary of participants' discussion concludes each section. Also, a taxonomy of lizards is appended.

In an introductory chapter, McLean, who is the originator of the "three brains of man" concept that proposes the evolutionary history of the human brain, describes the importance to brain scientists of research on lizards. Lizards, he explains, are distant relatives of long-extinct mammal-like reptiles that are believed to have been antecedents of today's mammals. Understanding the connection between brain and behavior in the reptilian brain is thus fundamental to understanding the structure and function of the more complexly developed primate brain.

Single copies of Behavior and Neurology of Lizards may be obtained while a supply lasts by writing Public Inquiries, NIMH, Room 11-A-21, 5600 Fishers Lane, Rockville, Maryland 20857. The volume will not be available for purchase from the Government Printing Office.

SECOND INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY

The Second International Congress of Systematic and Evolutionary Biology (ICSEB-II) will be held at the University of British Columbia, Vancouver, Canada, 17-24 July 1980.

The provisional list of symposia topics include:

1. Arctic refugia and the evolution of Arctic biota.
2. Origins and evolution of the North Pacific marine biota.
3. Evolution of reproductive strategies.
4. Evolutionary epigenetics.
5. Evolution of community structure.
6. Green algae and land plant origins.
7. Macromolecular mechanisms in evolution.
8. Allozymes and evolution.
9. Coevolution and foraging strategy.
10. Evolution of colonizing species.
11. Rare species and the maintenance of gene pools.
12. Paleobiology of the Pacific rim.

Additional symposia may be included.

Sessions for contributed papers and for papers in specialized fields, taxonomic as well as methodological will also be organized.

PYTHON BREEDING MANUAL

The Phython Breeding Manual, published by the Institute for Herpetological Research, is now available. A compilation of a two year, world-wide survey on captive propagation of pythons, the Manual is divided into four sections. The first section presents specific breeding data on eighteen species of pythons, including mating, egg-laying and hatching seasons, as well as other relevent data. The second section discusses methods of inducing python breeding. The third and

fourth sections discuss techniques of python egg incubation and incubator design and construction. General recommendations and other useful information for the python breeder are also included. The cost of the Python Breeding Manual is $6.00 U.S., plus $2.50 U.S. air or $1.25 U.S. surface for mailing and handling. Address inquiries to:

HR REPRINT POLICY CHANGE

Contributors to HR may no longer order reprints (see new editorial policy on inside back cover). In the past, reprints were supplied to contributors by simply xeroxing the amount requested. This technique was time-consuming, and was not consistent with the HR mission as a newsletter for the herpetological community. Further, contributors can produce their own reprints as cheaply as (or cheaper) than the HR staff.

MISSING HR ISSUES

If you do not receive an issue of Herp Review, DO NOT contact the editors for a replacement. Contact the Publications Secretary listed on the inside front cover.

Final Further Comments on the Calling of Common Names

Comments on "Common" Names

I am very glad to have an up-to-date list of species of amphibians and reptiles occurring in the United States and Canada, along with a list of subspecies currently recognized (SSAR Misc. Publ., Herp. Circular No. 7). The SSAR Committee on Common and Scientific Names must be congratulated for providing this service and should be encouraged to repeat it at intervals. The committee should also consider seriously the inevitable criticisms coming from those who disagree with parts of the list. It seems to me (that) thoughtful responses to the current version of the list can make subsequent versions more acceptable to those who wish to use the list, and it is in this vein that the following remarks are offered. In addition, because I am acknowledged for suggestions, corrections and criticisms, the implication might be that I find the list completely satisfactory. In fact, few of my suggestions were followed.

My criticisms fall into three areas: (1) orthography, (2) excessive contrivance of common names for taxa other than species (a practice carried over from the ASIH list) and (3) what I perceive as excessive concern that common names be "standardized."

The new list contains some abrasive (and grammatically questionable) changes in spelling. I suppose grammatical leniency in the interest of saving space encourages changes of this sort, but does not justify them. Some that made me cringe were smallmouth, blackbelly, longtail, graybelly, shovelnose, and redback salamanders and roughskin and redbelly newts. Other names fitting the same pattern were, for some reason, not shortened.

Orthographic changes are of less concern to me than the other, broader criticisms because I seldom use common names anyway and don't see the point of trying to standardize them excessively. The philosophy of the ASIH list was clearly described in its introduction: "Our selections should be considered recommendations only. These names have no official status, and their use is in no way compulsory. Workers who hold that common names have no place in scientific zoological literature may ignore them." This statement was coupled with the warning that failure to use any common names can frustrate people unfamiliar with the zoological names. We surely all understand this, but also understand that it makes no difference whatsoever in this context whether Gyrinophilus porphyriticus is called the purple salamander or the spring salamander, or whether Eurycea longicauda is called the long-tailed salamander or the longtail salamander. The really important part of these common names to people outside herpetology is the word "salamander." Names like snake, turtle, lizard, salamander and frog are truly "common" names understood by most English-speaking people. I can understand why the editor of a herpetological journal might not want an article to use the common name "spring lizard" or "ground puppy", or just "lizard," for salamander. I see no justification, however, in forcing a legalistic set of largely contrived English names, in parallel with zoological names at every taxonomic level, on either the public or on ourselves. Perhaps I have misread a mild authoritarian impulse into the SSAR list where none was intended.

My most serious criticism of the SSAR list is that it continues the practice of listing "common" names for genera and subspecies. Contrivance of English names for genera and subspecies is based, I think, on a misunderstanding of what "common" names are, and occasionally leads to absurdity and biological misunderstanding. Consider the following examples from the list: The common name for salamanders in the genus Gyrinophilus is "spring salamanders." Yet, only two of the three species in the genus are actually called spring salamanders in the list; the other is called "Tennessee cave salamander." Wouldn't it logically be called "Tennessee cave spring salamander" (heaven forbid)? Members of the genus Pseudotriton are called "red salamanders." Yet, P. ruber is called the "red salamander" and P. montanus the "mud salamander." Shouldn't P. ruber be called the "red red salamander" and P. montanus the "mud red salamander"? The common name suggested for the genus Eurycea is "brook salamanders." Yet, not one of the twelve species in the genus is called brook salamander. Does this really make sense to anyone? What is the value of these generic "common" names if no one uses them, or has to look them up in a list? The suggested names are mostly contrivances of herpetologists who seldom use them anyway. Neither the ichthyologists nor the ornithologists have found it necessary to use generic common names.

Ichthyologists and ornithologists have not found it necessary to coin common names for taxonomically recognizable geographic variation either. Use of common names for subspecies can cause the same sorts of absurdities that arise with generic common names. For example, the species Gyrinophilus palleucus is called, in the list, "Tennessee cave salamander," but none of the three recognized subspecies is. What is the utility of calling G. palleucus the "Tennessee cave salamander?" but G. p. palleucus the "pale salamander"? Other examples of this sort of thing are: no subspecies of the "eastern newt" is called eastern newt; no subspecies of the "striped chorus frog" is called striped chorus frog; no subspecies of "Gilbert's skink" is called Gilbert's skink. More importantly, it is misleading and, I think, educationally counterproductive to encourage laymen and young enthusiasts to think of subspecies as distinct "kinds" only slightly different from species, and this I believe "standardized common names" for subspecies do. We now know too much about the generic, ecological and evolutionary significance of geographic variation to encourage that kind of thinking any longer by coining an English common name for every zoological subspecies name in current use.

I hope these and other concerns about common names lists can be discussed thoroughly as future versions of the SSAR list are prepared.

RONALD A. BRANDON, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901.

Another View of the SSAR Common Names List

I disagree with Rossman, et al. (1978, Herp. Rev. 9(4): 146) and with Huheey (1978, Herp. Rev. 9(4): 146-7) in their main criticism of the recently published "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (Collins, et al 1978, SSAR Herp. Circ. no. 7). The same argument opposing the use of nouns as modifying words in common names was expressed to me a few years ago to support the use of the common name "hog-nosed snake" rather than "hognose snake" for snakes of the genus Heterodon. Today most herpetologists have accepted the name "hognose snake." I find the argument by Rossman, et al., to reject this list of names less than convincing since names in previous lists have many nouns and noun forms used as modifying words.

A common name is not a description but rather a verbal symbol for a species or subspecies. "Black-headed snake," as a descriptive term, refers to any or all snakes with black heads; but "black-headed snake," used as a common name, refers to certain species of the genus Tantilla and "blackhead snake" will serve this naming function just as well. I maintain that the grammatical rules for a descriptive statement are irrelevant for a name (I am not discussing the rules for composition of a scientific name which are explicitly stated). A common name should be judged on how well it serves as a name. It should be judged for ease of remembering, distinctiveness, shortness, ease of pronunciation and ease of spelling. Whenever possible the name should include words that are logically associated with the species for ease of remembering.

The arguments expressed by Rossman, et al., for using only the hyphenated participial form do not hold up under scrutiny:

1) Hyphenated participial forms are less awkward. The context suggests that they mean awkward sounding or awkward in pronunciation. Hyphenated participial forms are not inherently less awkward. Which is more awkward to pronounce: "flat-headed snake" or "flathead snake?"

2) Hyphenated participial forms are less ambiguous to the non-herpetologist. But the meaning of a name is the species for which it stands and does not depend upon the preciseness of its descriptive words. The example cited by Rossman, et al., is trivial compared to the ambiguity of some other well-accepted common names. Should "crayfish snake" be changed to "crayfish-eating snake," "rat snake" to "rat-eating snake," etc. to avoid ambiguity? And what should be done with "fox snake" and "garter snake?"

Rossman, et al., criticize the recently published list for being inconsistent. After reading the rationale by Collins, et al. (1978, Herp. Rev. 994): 147), I do find a few inconsistencies in the application of the stated guidelines. However, the new list follows a set of guidelines more consistently than either Stebbins (1966, "A Field Guide to Western Reptiles and Amphibians") or Conant (1975, "A Field Guide to Reptiles and Amphibians of Eastern and Central North America"), authorities which Rossman, et al., recommend. Stebbins uses "hognose snake" on one page and "leaf-nosed snake" on the next. Conant uses "ringneck snake" and "rose-bellied lizard." Many other examples could be given.

I urge the adoption of this new list of standard English common names by herpetologists. I am not completely satisfied with all of the names included but I think it has much to commend it. I do not advocate eliminating the use of other colloquial names, especially in regional works, but I think it is important to also use standard names to avoid confusing the layman who finds scientific names foreign.

I also urge the Committee on Scientific and Common Names to develop a set of guidelines for standard common names utilizing criteria of effectiveness and ease of use, and then to use these guidelines in the next revision of the list rather than rules that have little relevance to the function of a name. These guidelines should include the first four guidelines in the present list (p. 1) which ensure that wherever possible the standard common name will be the same as or similar to a name in widespread use. Therefore any revision will necessarily be conservative. And I hope that future changes will be minimal because the benefits of stability, even for common names, is great. Additional guidelines might include a limit on the length of a name, guidelines for combining words in a name (why use the combination "king-snake" but not the combination "milksnake?"), elimination of the hyphenated form except where the hyphen is necessary to prevent awkward construction, elimination of the possessive form, etc.

I agree with Huheey that it makes little difference in communication whether the hyphenated participial form or the non-hyphenated noun form is used. Maybe a list of standard English common names will need to include alternative forms in order to satisfy all members of our fraternity.

The above discussion should not be taken as an argument for loose usage of the English language. I agree with Rossman, et al., that "the scientific community should support proper usage of the English language, not contribute to its deterioration." I strongly support adherence to good grammatical usage for effective and accurate communication in scientific writing. However I see no benefit in applying arbitrary rules to the formation of a proper name which rules are irrelevant to the function of that name in communication.

Current Literature

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

A new feature of Current Literature is the inclusion of senior author addresses. Although only a small portion of the citations have the addresses included in this issue, it is a goal to publish addresses for a majority of the citations for Current Literature in 1979.

Richard D. Worthington, Current Literature, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968.

THE SOUTH AMERICAN HERPETOFAUNA:
ITS ORIGIN, EVOLUTION AND DISPERSAL

Museum of Natural History, University of Kansas Monograph No. 7. William E. Duellman (editor). Approx. 490 pages and 172 illustrations, soft-bound. Anticipated December 1979.

This book embodies the results of a symposium held in Lawrence, Kansas, in August 1977. Sixteen chapters by noted authorities cover such topics as: Cenozoic faunas of South America and faunal relationships with Africa and Australia, Quaternary biogeography of South America, regional analyses of herpetofaunas, and conservation.

PRE-PUBLICATION PRICE: $20.00 (for orders received prior to 30 November 1979). POST-PUBLICATION PRICE: $25.00. Please make checks payable to: Publications, Museum of Natural History. Send orders to: Publications Secretary, Museum of Natural History, University of Kansas, Lawrence 66045. Include 50¢ for handling for each copy purchased. Kansas residents add 3.5% sales tax.

ORDER FORM

Please send me ____ copy(ies) of KUMNH Monograph No. 7, The South American Herpetofauna: Its Origin, Evolution and Dispersal. Enclosed is my check for $_____.

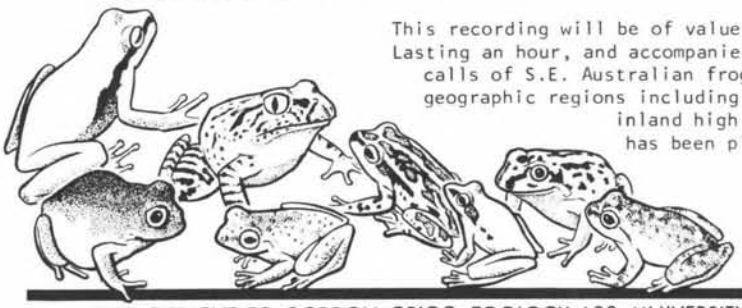
A FIELD GUIDE TO

AUSTRALIAN FROGS

BY JOHN BARKER AND GORDON GRIGG



This field guide to the 150 species of Australian frogs is lavishly illustrated with 161 colour photographs, line drawings and distribution maps. The text consists of introductory chapters on the evolution, taxonomy, and zoogeography of Australian frogs and detailed descriptions of individual species, arranged by family and including notes on general biology. Keys are included also, and there is a glossary of technical terms. The book is hardcover, and on glossy paper.

Cost air mail US$26.00

FROG CALLS OF S.E. AUSTRALIA

A CASSETTE TAPE RECORDED BY GORDON GRIGG AND JOHN BARKER

This recording will be of value and interest to many herpetologists. Lasting an hour, and accompanied by a booklet, the tape consists of calls of S.E. Australian frogs (44 species) grouped according to geographic regions including frogs of the desert, high mountains, inland high plains and coastal areas. Emphasis has been placed on the diversity of calls, and commentary on the tape discusses their biological significance.

Cost air mail US$ 9.00

SEND PAYMENT TO GORDON GRIGG, ZOOLOGY A08, UNIVERSITY OF SYDNEY 2006, N.S.W. AUSTRALIA

Personal checks in US dollars accepted.

ARE YOU CERTAIN THAT THE SPECIMENS YOU OBTAINED ON YOUR LAST COLLECTING TRIP WERE NOT PROTECTED OR CONTROLLED BY STATE REGULATIONS?

Did you realize that Alabama regulates the collection of 221 plant and 377 animal species, Michigan controls 117 species, Oklahoma controls 351 species? The majority of states have regulations which apply to the acquisition of scientific specimens.

Determining what species are controlled in various states is difficult and time consuming. In order to help you deal with this problem, The Association of Systematics Collections will soon be making available the:

Directory of State Protected Species:
A reference to species controlled by non-game regulations

This Directory contains listings of regulated plant and animal species for each of the 50 states and the Virgin Islands. In addition, for each state, the Directory includes:

1. Federal Endangered or Threatened status for all of the state-listed species.
2. Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) status for all of the state-listed species.
3. State/Federal endangered species cooperative agreement information.
4. Requirements for scientific collecting permits.
5. Addresses and telephone numbers for state permit granting agencies.

If you are involved in the collection or acquisition of plants and/or animals within the United States for scientific purposes, or if you work for any of the zoos, museums, or universities with active collecting programs, this is an invaluable source of information.

This Directory is available to persons affiliated with ASC member institutions for $17.50. The price for persons not affiliated with ASC member institutions, until 30 April 1979 is $37.50; after 30 April 1979 it will be $50.00.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½X11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8X10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, HR Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

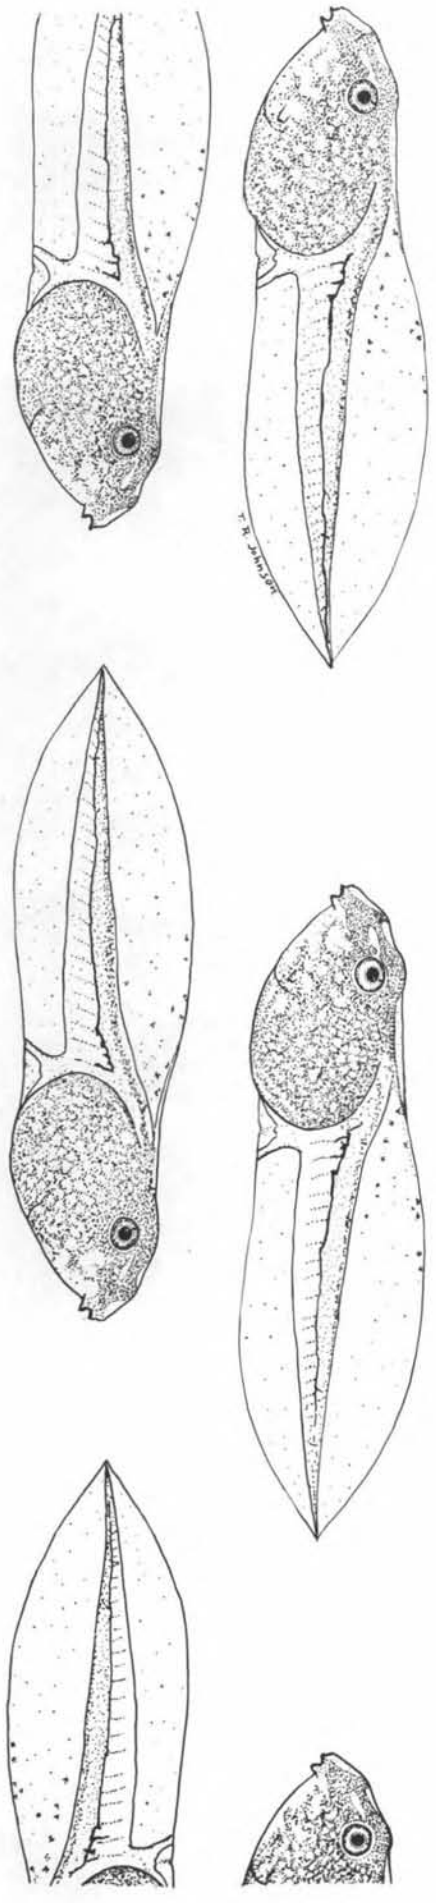
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member . . .	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

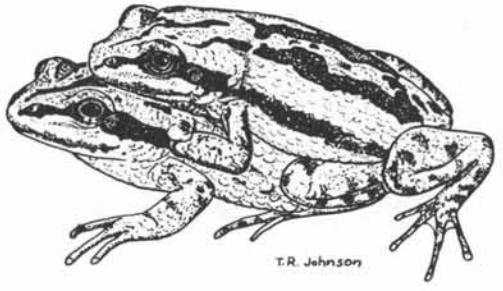
SSAR GRANTS-IN-HERPETOLOGY

The SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES is pleased to announce the establishment of SSAR GRANTS-IN-HERPETOLOGY, a new society program designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. Four grants of $200 each will be available for awarding at the Annual Meeting of the SSAR. Grant proposals will be considered in the following areas: 1) HERPETOLOGY-ORIENTED CONSERVATION, 2) GRADUATE STUDENT HERPETOLOGICAL RESEARCH, 3) REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS, and 4) HERPETOLOGICAL RESEARCH IN ZOOS.



Members of the SSAR Grants-in-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Harry W. Greene (Chairperson), C. Kenneth Dodd, Jr. (Conservation), Stephen R. Edwards (Graduate Student Research), Martin J. Rosenberg (Regional Herpetological Societies), and John Behler (Zoo Research).

All proposals must be typewritten and submitted in duplicate no later than 1 APRIL 1979 to:

Harry W. Greene
Museum of Vertebrate Zoology
University of California
Berkeley, California 94720

Individuals submitting should designate to which of the four areas their proposal applies. Additionally, proposals from graduate students, individuals representing regional herpetological societies, and individuals representing zoos should be accompanied by a letter of support from the institution or regional society represented. All proposals should be brief (2-3 typed pages), and should include a statement of the problem, objectives and methods.

Participation in this SSAR program is limited to SSAR members regardless of sex, race, creed, or religious affiliation.

In Memoriam

HOWARD KAY GLOYD
1902-1978

A warm, cherished friendship that flourished for almost half a century terminated on August 7, 1978, with the death of Howard K. Gloyd, fondly known as "H. K." to his many friends and associates.

It began in 1929 when a callow youth with an enthusiasm for reptiles and a job as a keeper in the Toledo Zoo started making pilgrimages to the University of Michigan, then widely recognized as the herpetological mecca of the United States. The persons with the great names--Ruthven, Gaige, Blanchard, and Case--were helpful and encouraging, but it was with the graduate students that I developed the greatest rapport. Howard Gloyd was preeminent among them.

How long ago that seems now and how ambitious we were in those days. All sorts of schemes and projects entered our youthful heads. H. K., ever ready to share his knowledge and enthusiasm with his friends, was then deeply involved with rattlesnakes, but that didn't deter him from also aspiring to monograph the other pit vipers, notably Agkistrodon. As our close relationship flowered, he suggested making a joint assault on that group on a worldwide basis, and I eagerly accepted. We published two short papers while he was still in school, and I, naively, remarked that perhaps the combination "Gloyd and Conant" would someday be as well-known as "Baird and Girard." He often twitted me about that, but I think he secretly hoped it just might come to pass.

Over the decades we were each other's most voluminous correspondents, we seldom missed a chance to be together, even for a few hours, and we often turned to each other, like affectionate siblings, for help and advice when the going was rough.

Howard Gloyd was born on February 12, 1902, at DeSoto, Kansas. He was an only child, and his parents were well along in years at the time. His father, Winfield Scott Gloyd who was a harness maker, was past 50 and his mother, Melvina (Skaggs) Gloyd, was nearly 46. He developed an interest in natural history at a very early age that was encouraged by his mother, who often went hiking and canoeing with young Howard and his friends. At the age of 12 he was an accomplished taxidermist; by 1918 and again in 1919 a large number of his well-mounted birds and mammals, including a swan, owl, eagle, and coyote, were prominently displayed in the window of the hardware store in Wellsville, where the family then resided. His youthful talents and

1. Howard K. Gloyd, Ph.D., Director of the Chicago Academy of Sciences, in his office in 1939.

life-long passion for field work were enthusiastically nurtured by Grace R. Meeker, the public librarian at Ottawa, Kansas, where he lived as a young man. She was a competent naturalist with a major interest in botany, especially mosses, and she, probably more than anyone, broadened H. K.'s horizons to include many facets of natural history and not just the birds, which had been his first love. He always referred to her with fondness as "Aunt Grace." His carefully prepared collection of about 200 bird study skins, incidentally, was acquired by the University of Michigan in 1930.

It was inevitable that young Gloyd would pursue a college career. His father, mindful of his own long hours and hard work, was pleased and not a little surprised to realize his scholarly son was being paid to teach at Ottawa University, the institution from which Howard received his B.Sc. in 1924. H. K. was awarded his M.S. from Kansas State College, Manhattan, in 1929, and his Ph.D. from the University of Michigan in 1937. Ottawa University presented him with an honorary D.Sc. in 1942.

Howard Gloyd's professional career can be divided conveniently into three periods: (1) his academic years and relationship with Frank Nelson Blanchard; (2) his long tenure as Director of the Chicago Academy of Sciences; and (3) his position on the faculty of the University of Arizona at Tucson.

Copperheads and rattlesnakes, as well as a wide variety of other serpents, were abundant among the rocky limestone ledges and wooded areas of eastern Kansas, but it was not until 1924 that H. K. began collecting and studying them in earnest. His intimate acquaintance with the two venomous species was the springboard for his life-long interest in pit vipers, and his meeting with Blanchard at the University of Michigan Biological Station at Douglas Lake in 1927 led eventually to the taxonomic investigations that were his forte for the remainder of his life. He described eight new forms of rattlesnakes and 11 other new pit vipers, as well as a new genus. He published 75 papers in herpetology (one will be posthumous), all of which are listed in the reprinting of his spendid work, "The Rattlesnakes" (Chicago Acad. Sci., Spec. Publ. No. 4, 1940), that will soon be available through SSAR. He also wrote 20 other papers, chiefly on birds. Four taxa, one each in the genera Crotalus, Elaphe, Heterodon, and Sonora, as well as three species of insects, bear the designation gloydi.

Blanchard was brilliant in many ways and a perfectionist and, once a person became well acquainted with him, an inspiring teacher as well. Invariably, however, one's first impression was of an austere, unfriendly man, and H. K. almost went home in disappointment despite the gracious correspondence that previously had passed between them. As a candidate for his doctoral degree, Gloyd was strongly influenced by Blanchard and was easily his most distinguished student. They developed a mutual respect that endured until Blanchard's untimely death in 1937 a few months prior to his 49th birthday.

Partly because such a work was needed and partly because of the success of Blanchard's Key to the snakes of the United States, Canada, and Lower California (Mich. Acad. Sci., Pap. 4, 1925), the two of them decided to prepare a handbook on the snakes of the same large area. Toward that end they visited many museum collections together and undertook a long field expedition, chiefly through the South and West, from September, 1935, until February, 1936. H. K. often regaled his friends with accounts of his adventures in the field with Blanchard, who was so extremely timid and un-

2. Gloyd in the field in the Southwest in 1935 in the outfit that prompted Frank N. Blanchard to call him the "dude snake hunter." H. K. loved field work and thousands of his herpetological specimens have been deposited in more than a dozen museums.

sure of himself that several ludicrous situations developed. The handbook project, unfortunately, was never completed, partly because Blanchard died so soon afterward, and Gloyd, late in 1936, had accepted the position as Director of the Chicago Academy of Sciences.

I admired H. K. for all he did at Chicago despite the many difficulties he had to face and the slender resources at his disposal. The Academy, although it had a long tradition as a respected scientific institution, was tiny compared with the massive Field Museum, and it had little financial support from local citizens, many of whom thought one natural history museum was enough. Funds were always short. The staff was inadequate. He had both a board of trustees and a board of scientific governors with which to cope and whose members represented a diversity of personalities and interests. The effects of the depression years had to be endured, although help, provided through such agencies as the WPA, enabled the Academy to catch up with some of its deferred maintenance and to undertake a few new activities. One of those was printing, and with hand set type and a primitive press operated by an old-time journeyman printer, H. K. accomplished wonders. He edited and even wrote a fair portion of several journals, including the Academy's Bulletin and Special Publications, the Chicago Naturalist, and Natural History Miscellanea, the last of which he developed into a nationally recognized and widely used outlet for short papers, chiefly but not confined to herpetology. The early issues of Herpetologica were set by hand and printed at the Academy. With it all, Gloyd found time to complete his long work on the rattlesnakes, the broad nucleus of which was based on the material he had assembled while preparing his doctoral thesis at Michigan.

It was perhaps unfortunate there were two giants in the field at the same time. While Gloyd was earning an outstanding reputation for himself in the Midwest, Laurence M. Klauber was emerging as an authority on Crotalus in the West. They were always polite and exchanged information, but there was a reserve and wariness nonetheless that precluded any real friendship or collaboration. They tacitly agreed that Gloyd should handle the genus Sistrurus and the eastern species of Crotalus, whereas Klauber would concentrate on the West. Klauber's strong personal financial resources enabled him to hire whatever help he needed for his research and to do many things that were impossible for Gloyd to undertake. There was no National Science Foundation or similar large granting agency in those days.

3. Gloyd's research on the Asian species of Agkistrodon (sensu lato) occupied much of his attention during his years at the University of Arizona.

A fact often overlooked by herpetologists is that the Chicago Academy study collection is especialy rich in crotalid snakes that H. K. assembled and a large number of which he preserved and catalogued himself.

Nathan Smith Davis III, M.D., who had been President of the Chicago Academy of Sciences for 18 years, died in 1956. As so often happens when a strong leader succumbs, a new clique among the trustees gained power and basic policies were changed. Gloyd wisely avoided open conflict, and he left Chicago in 1958 to become a faculty member at the University of Arizona. He was no stranger to the Southwest to which he had repeatedly made field trips for decades. He was, in fact, very much at home and relished being in a warm climate far away from the wintry blasts from Lake Michigan. And finally, after a long struggle as an administrator, he achieved the profession for which he was most admirably suited--teaching and interpreting vertebrate zoology, zoogeography, herpetology, and natural history of the desert. He held the post of Director of the Traveling Science Institute of the Arizona Academy of Science during 1959-60, served actively on the Publications Committee of the University of Arizona Press from 1961 until 1974, and taught formal classes until he was 72. Meantime he continued his research on Agkistrodon, a project from which I had resigned in the late 50's leaving the field to him alone.

Howard Gloyd was an extremely likeable person. His friendliness and warm personality appealed to everyone, as did his subtle sense of humor. He always took time to discuss matters of mutual interest with his close friends and serious students no matter how many pressing items might be awaiting his attention. He made a host of friends during his lifetime, and he was still corresponding with some of his boyhood chums until a few months before he died.

H. K. was not all professional work and science. He had a variety of talents and interests. He was an excellent wood worker, and there are several pieces of furniture in his home that he constructed and which would be a credit to a cabinet maker. He was a fine photographer, and he developed an apparatus for portraying venomous and other snakes on a ground glass base in such a way as to eliminate all shadows. He did his own darkroom work. In a sense he invented the "snake pullman," which almost all herpetologists used for decades for transporting and shipping live reptiles. He had seen snake boxes with hinged tops, but it was he who added the extra, internal wire lid that provided a distinct safety feature. Because of his interest in firearms he at first used wooden shell boxes with their sturdy dove-tailed corners; later he designed and built many "pullmans," large and small. While he was at Ottawa University, he was bitten on the finger by a prairie rattlesnake

about 20 inches long. In the custom of the day, potassium permanganate was used as a treatment, and, as a result he suffered acute pain and tremendous swelling, but he eventually made a complete recovery. It was his first and last snake bite.

He collected firearms, chiefly hand guns, and greatly enjoyed using them. He owned a 22-caliber rifle when he was 10 years old, soon afterward acquired a short, smooth-bore pistol, and he had a shotgun when he was 13 or 14. He was adept at shooting lizards in the field.

Perhaps his favorite hobby and the one from which he derived the greatest pleasure was music. He was a percussionist and a talented one. He played drums when he was in grade and high school, was a member of the town band, and performed with musical organizations ranging from symphony orchestras to Dixieland bands. For a decade, beginning in the late 1940's, Thursday nights were the occasions for jam sessions in the basement of the Chicago Academy. There, the Academic Cats held forth with a full complement of the Dixieland instruments, and every one of the players held a Ph.D. They did so well that such musical greats as Muggsy Spanier sometimes sat in with them. Almost to the time of his death, H. K. enjoyed watching and listening to musical programs on television, such as the "Boston Pops" concerts, but it was a matter of sadness to him that his hearing had deteriorated to the point where he no longer could hear the piccolo when Sousa's rousing "Stars and Stripes Forever" was played.

Gloyd's many talents earned him numerous honors and awards. He was a member of Sigma Xi, Phi Kappa Phi, Phi Sigma, Gamma Sigma Delta, and Phi Mu Alpha (Sinfonia). He received three grants from the National Science Foundation to assist his work on Agkistrodon. He was a Fellow and Fifty-year Member of the American Association for the Advancement of Science, and he was long listed in American Men of Science and Who's Who in America. He became Professor Emeritus at the time of his retirement from the University of Arizona faculty.

In several ways H. K. was quite old-fashioned. He refused to use the two-letter designations for states recommended by the Postal Service. Until recent years he always shaved with a straight razor, a remarkable accomplishment in the eyes of most of us and now a dying art. Unlike his fellow Kansans and their neighbors from western Missouri who made a fetish of springing into action before sunup (remember Harry Truman's early morning walks around Washington?), H. K. was a late riser. He loved to read on almost any topic, but numbered among his favorites were herpetological, ornithological, and other natural history literature, biographies, which he especially liked, whodunits, and the delightful fantasies of J. R. R. Tolkien. Much of his research was undertaken during the evening hours, which were usually free from interruptions, and, that, in addition to his reading tended to make him something of a night owl. Despite his quiet friendliness, he was also a "loner" who enjoyed spending long hours by himself.

Howard Gloyd was married twice, first to Leonora K. Doll from 1925 to 1947 and by whom he had two children, Helen Katherine and Roger Scott, the latter named for me and his father. His second wife was Kathryn J. Stephenson, his widow; they were married almost 31 years. In his usual modest way he insisted on no funeral service, but he suggested that, instead of flowers or other ephemeral tributes, his friends and colleagues might wish to contribute to the Nature Conservancy General Fund, 1800 N. Kent Street, Arlington, Virginia 22209.

H. K. has left us, but I shall be working with him, in a sense, for a long time to come. His failing health made it obvious that he would not be able to complete his monograph on Agkistrodon and its related genera without help. So with his consent, I re-entered the project in late 1976, and will endeavor to finish the research we envisioned in the days of our youth. He has done an enormous amount of work on it, especially in searching the literature and compiling accounts of the many taxa. His careful studies on the Asian members of the group are quite thorough despite the language difficulties and the political "curtains" that made communication with Russian and Chinese herpetologists impossible for decades. His files and banks of data are in perfect order and a joy with which to work. I hope I can do justice to his second major opus - the rattlesnake monograph, of course, was the first.

Personally, my loss is great. There is no longer the warm presence, the kind and understanding friend who was ever ready with help and advice whenever I needed it. How many of us can boast of a close and valued professional companionship that lasted almost 50 years?

ROGER CONANT, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131.

T.R. Johnson

THE HERPETOLOGICAL COLLECTIONS OF THE STRECKER MUSEUM

Strecker Museum's beginnings date from the 1850's, although the collections were not officially designated as a museum until 1893 (Brown, 1976). Strecker Museum has a long history of involvement with research in herpetology; John K. Strecker, Curator of the Strecker Museum (then known as the Baylor University Museum) from 1903 until his death in early 1933, is considered to be the "Father of Texas Herpetology." He also furthered herpetology throughout the nation during his curatorship at the museum. Curators since Strecker have done much to continue the strength of Strecker Museum's herpetological collections. The current Director and Chief Curator of the Museum, Dr. Bryce C. Brown, has added considerably to these collections, especially through extensive field work in Mexico.

Since a recent report (The Committee on Resources in Herpetology, 1975) contains incomplete and inaccurate data on the herpetological holdings of the Strecker Museum, a current summary of the museum's collections seems necessary. Also, in a recent listing of museum acronyms (Electronic Data Processing Subcommittee, Herpetological Resources Committee, 1978), BAYUM was listed for Baylor University Museum, a name and acronym not in use since the 1940's. There was no listing for Strecker Museum (SM).

The SM collection contains approximately 45,000 fluid preserved and skeletal specimens, about equally divided between reptiles and amphibians. This includes the former Texas Christian University (TCU) herpetological collection which was donated to Strecker Museum in 1972. The TCU acronym was also not listed by the Electronic Data Processing Subcommittee.

Geographical emphases of the SM collection are United States (70%, with a strong emphasis on Texas) and Mexico (25%). Special collections include field notes, cleared and stained specimens of the troglodytic Eurycea species, and a series of live exhibits which includes approximately 50 specimens. Type specimens (holotypes and paratypes) total 57.

The SM collection data are currently being stored in the museum's new computer. When completed, this will allow a wide variety of indices (geographical, taxonomic, collector, etc.) to be obtained with ease.

The Fourth All-Union Herpetological Conference of the USSR

The Fourth Herpetological Conference was held at the Zoological Institute of the USSR Academy of Sciences in Leningrad on February 1-8, 1977. Two hundred thirty-six scientific workers from scientific research institutes of the USSR Academy of Sciences, Academies of the Union Republics, Ministry of Health, Ministry of Agriculture and from universities and higher schools of the USSR took part in the Conference. The participants received a greeting telegram from the American Society of Ichthyologists and Herpetologists and from a number of foreign colleagues.

The Conference discussed a wide range of problems concerned with systematics, ecology, ecological physiology, geographic distribution, faunal history and economic importance of Amphibia and reptiles in the native fauna. The conference reviewed the results of herpetological development in the USSR since the Third Conference (1973) and outlined the vital aims and ways for further development. Proceedings of the conference were published in a book of collected abstracts titled The Problems of Herpetology (Leningrad 1977).

The main plenary report "Herpetology in the Soviet Union in 1973-1976" was delivered by I. S. Darevsky, the chairman of the All-Union Herpetological Committee. The speaker emphasized that during the recent year, about 260 different herpetological articles were published in the USSR, which is an increase of one fourth over the number of works published during the four-year interim between the second Conference and the third. During this period, 25 herpetological theses were defended, not to mention some special toxicological theses. Considerable success was achieved in faunology. New species of lizards and snakes were discovered in the USSR fauna. Many new faunistic findings considerably widen the previously-known ranges of several species. Identity of several reptile species was proved by karyological and biochemical analyses. The study of systematics and taxonomy, comparative morphology, anatomy and karyology of Amphibia and reptiles was successful. Research on hybrid and intergrading populations was carried out. A comprehensive contemporary research project was carried out on the ecology of numerous landscape species (i.e., the most typical and common indigenous species), and on those of venomous snakes whose venoms are used in pharmacology. Ecto- and endoparasites of Amphibia and reptiles were studied. Some rare and endangered species were revealed and inserted into the "Red Data Book" of the USSR.

The contribution of Soviet paleoherpetologists is great. In addition to ancient groups, they also study more recent though extinct forms.

Among the numerous publications, one should especially note the collective monograph "The Sand Lizard (Lacerta agilis)" published in 1976. In the nearest future, monographic descriptions of some other widely distributed species of the USSR fauna and neighboring countries will be published in the same series. Work on compiling the "Catalogue of Amphibia and Reptiles" of the USSR will also be started.

The first plenary session dealt with the principles of reptile phylogenetic classification. L. P. Tatarinov (Moscow) widely discussed the extent and limits of Class Reptilia. In particular, he paid attention to the necessity of distinct definition of the initial stage of reptile evolution from the moment when such a class appeared. The speaker expressed an important idea that this stage and the beginning of higher vertebrate divergence should be referred to the phylogenetic level preceding the appearance of Seymouriamorpha. It was mentioned that transferance of several transitional forms and groups from one class to another or treating them as

independent classes, as suggested by taxonomists, does not solve the problems of phylogenetic classification.

L. I. Khozatsky (Leningrad) read a report on construction of a reptile system. Working out a phylogenetic classification of any group of organisms should be in itself a synthesis of objective data on lines (directions) of evolutionary development of interrelated groups and about taxonomic extent and rank of each of them. Any taxonomist should base his suppositions on the unity of interrelated characters of the studied organisms--morphological, physiological and ecological. With due regard for these general ideas a scheme of the main taxonomic subdivisions of Amniota is given, which should be distinctly divided into two superclasses: Therapsida and Saurapsida. The first should include: Theriamorpha and mammals and (supposedly) a class of Euryapsida (Ichthyopterygia and Synaptosauria). It was suggested to separate the superclass Sauropsida into the following classes: Anapsida (diadectomorphous Cotylosauria and turtles), Dinosauria, Pterosauria and true reptiles (Lepisauria, Thecodontia and Crocodilia) and birds.

M. N. Iordansky (Moscow) considered the problem of the origin of snakes. After detailed osteo- and mycological research on jaw apparatus in lizards and snakes, he arrived at the conclusion that snakes were most closely related to geckos (not to monitors as commonly accepted) and appeared probably from an ancestral stem "protogecko." The paper of N. N. Shcherbak and M. L. Golubev (Kiev) contained results of taxonomic analysis of several genera and subgenera of geckos of the Gekkonidae fauna of the USSR. L. L. Borkin (Leningrad) and A. L. Mazin (Moscow) investigated interdependence between the quantity of nuclear DNA and systematic rank and ecology of Amphibia on different taxonomic levels from that of the Class to the geographic population, on the basis of their own results (most Amphibia species in the USSR) and of published data. They have confirmed positive correlation between the quantity of DNA and minimal developmental rate and shown intraspecific geographic variability of genome size. A. T. Toktosunov and E. Y. Masik (Frunze) have studied different populations of the toad Bufo viridis from karyological aspects in Kirghizia. While lowland populations are diploid, the typical forms of toads, Tien Shan high mountain green toads were tetraploid which was the reason for their adaptability to unfavorable parameters of the environment. N. I. Solomatina (Moscow) has examined pecularities of reptile skull and biomechanisms of their jaw apparatus.

I. A. Antipchuk (Melitopol) carried out comparative-morphological research on the lungs of crocodiles and birds and has established homology of respiratory organs of these groups. By means of the electron microscope, N. B. Ananieva and N. E. Mikkau (Leningrad) have studied skin receptors of different lizard species. Having studied ontogenetic rebuilding of the sublingual apparatus in Amphibia, A. S. Severtsov (Moscow) has revealed the historical changes of morphogenetic processes in the course of metamorphosis.

The problems of ecological physiology and behavior of Amphibia and reptiles were reflected in the paper by E. D. Vassiliev and S. V. Smirnov (Moscow) on the ear and hearing of lizards, snakes and turtles. V. E. Sokolov and V. P. Sukhov (Moscow) applied radiotelemetric methods and have studied daily changes of movement activation and body temperature of the tortoise Agrionemys horsfieldi. Other papers and reports contained interesting information on physiology and behavior and on morphology of Amphibia and reptiles.

Particular attention being paid to the problems of ecology, a special session dealt with them. Papers of the following authors should be mentioned: V. I. Garanin (Kazan) about the role of Amphibia and reptiles in biocoenoses of anthropogenic landscape (i.e., habitats changed as a result of intensive human activity), V. G. Ishchenko (Sverdlovsk) about productivity of populations of tailless Amphibia, L. G. Apostolov and co-workers (Dnieperpetrovsk) about energetics of trophic relations of these Amphibia.

A comprehensive investigation of peculiarities of Amphibia and reptiles existing in natural surroundings and under conditions of anthropogenic landscape was performed and the number of representatives of several species was calculated. On the basis of these results, principles and concrete recommendations on protective measures for these animals are being worked out. The Conference has adopted a list of rare and endangered species of Amphibia and reptiles to be included into the "Red Data Book" of the USSR as reported by A. G. Bannikov (Moscow). Great importance was attached to the problems of toxicology. Review of the papers on this topic will be published in "Toxicon," the journal of the International Toxicological Society.

At the final plenary session, the participants of the Conference listened to an interesting report including a showing of many slides by N. N. Drosdov (Moscow) about the herpetofauna of desert regions in Australia. At the same session, interesting reports were read by foreign herpetologists--G. Dobrovolska (Warsaw), L. Berger (Poznan), G. Deli (Budapest), G. Peters (Berlin).

The concluding item of the Conference was adoption of a detailed resolution which reflected the most important achievements of Soviet herpetology and outlined ways of its further development. Professor I. S. Darevsky, the head of the Laboratory of Ornithology and Herpetology (Zoological Institute of the USSR Academy of Sciences), was again elected chairman of the Herpetological Committee.

I. S. DAREVSKY and N. N. SCHERBAK, Zoological Institute, Academy of Sciences of the USSR (Leningrad) and Institute of Zoology, Academyof Sciences of the Ukrainian SSR (Kiev).

Rebuttal to Smith and Kohler on Introduced Species

In a recent edition of the Transactions of the Kansas Academy of Science (Vol. 80, nos. 1-2, pp. 1-24), H. M. Smith and A. J. Kohler published "A survey of herpetological introductions in the United States and Canada". As is Dr. Smith's usual style, it is a very thorough and well-researched study of the subject. The body of the paper, however, proposes several alarming or, at the least, debatable points of philosophy that I feel should not go unargued.

The main points that I disagree with are as follows:

1) I find a central theme throughout the paper that introduction of non-native forms is or can be beneficial, if populations of same are thoroughly monitored and researched prior to their introduction. This may be weakly plausible; however, there is an inherent assumption here that only competent researchers will be responsible for such introductions. Unfortunately, there is a long and well-documented history of most of the introductions into the United States being done by those with little or no competence in any biological field (i.e., pet dealers, their customers, etc.). This has been and most likely will continue to be the major source of exotic animal pollution in this country, and shows all the more need for stricter regulation in this area.

2) I strongly disagree with the concept that introductions "should be encouraged when preliminary, thorough, broadly perceptive appraisals suggests a high probability of success and a minimum risk to existent diversity" (emphasis mine). I contend that the state of the art today precludes the possibility of such thorough, broadly perceptive appraisal. We are just beginning to

understand the basic biology of only a tiny percentage of native species, much less exotics. For example, how well known are the exact niche requirements for such forms as Diadophis punctatus, Plethodon glutinosus, or the Rana pipiens complex? I dare say many of us could say where and when these forms could be found, but how many, if any, could say exactly why? To propose the introduction of even more poorly known exotics at this time seems to me irresponsible.

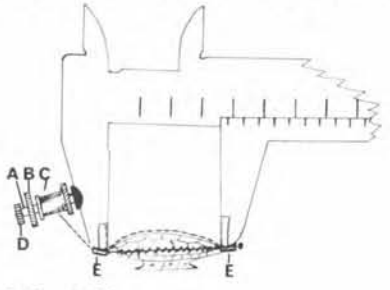
Smith and Kohler did not touch upon risks to future diversity. Is it not logical to assume that if an introduced species has successfully occupied a particular niche that this precludes the availability of that niche to any future populations of native forms into which to adapt? As the authors themselves put it, "The unoccupied niches that exist... are...very crudely understood."

3) I disagree also with the idea that dilution of the genome is the most deplorable aspect of introductions. While certainly it is an important consideration, the possible reduction or extinction of native species has to be an even more important consideration. Smith and Kohler themselves remark that "native diversity is a precious heritage any diminution of which diminishes ourselves."

The authors have also passed over rather lightly the negative aspects of certain introduced species, such as Bufo marinus and Xenopus laevis. B. marinus is considered a hazard and pest throughout much of its range, competing with and/or consuming many individuals of native anurans, small mammals, and the like. Its ability to poison humans is well known. The depredations of Xenopus larvae on native amphibian larvae in the southwestern United States have been shown to be extensive and, in certain cases, quite complete. The deadly properties of Dendrobates toxins are also well known and the establishment of such an attractive animal in Hawaii must surely be treated with some alarm.

My final objection is this: Smith and Kohler are proposing, if you will, a form of "ecosystem engineering" with all the inherent risks that have been shown with genetic engineering, and perhaps with even greater, more subtle dangers than are present there. Genetic engineers deal in a level of precision that organismal and evolutionary biologists can only dream about, and yet much of their work is a matter of hit-and-miss or hope-for-the-best. We have a moral obligation, at this point in time, and considering the current state of environmental affairs, to protect at all costs what little we have left of our natural heritage. To tamper with that heritage via introductions of non-native animals into the United States seems to me, again, irresponsible.

ERIC M. RUNDQUIST, 1612 Tennessee, Lawrence, Kansas 66044. ●



A Modification of Vernier Calipers for Measurement of Convex Curved Surfaces

Accurate measurement over a curved surface is at best difficult. Most systems employed are beset with problems of convenience and accuracy. The use of a string or wire stretched over the curve and then compared to a linear scale is inaccurate and difficult on small specimens. The modified vernier calipers described below overcome both problems. The calipers have been fitted with a flexible filament which conforms to a convex curve and is then stretched tight by sliding the jaws of the calipers apart. The distance along the curve is read as a linear measurement on the standard scale of the calipers. Specific application has been to the measurement of curved length and curved width of embryonic marine turtles. This application has provided two measurements in one operation: straight distance and distance along the curve of the carapace.

Modification

Figure 1 provides a detailed view of the modifications necessary to adapt standard vernier calipers for the measurement of convex curves.

The central pin (A) is a threaded piece which has been silver soldered to the calipers. The pin was fitted with a free moving, flanged spool (C), a threaded locking nut (B), and a retaining cap (D). The spool was fashioned to have a larger bottom flange which allows the spool to be turned and a small top flange which retains the filament. The locking nut moves on the threads of the central pin and can be secured against the spool. The bottom flange of the spool and the locking nut were knurled to provide a non-slip surface for easy movement. The retaining cap was spot welded to the central pin. Two stainless steel guide tubes (E) were silver soldered to the tips of the outside diameter prongs of the calipers.

A Threaded Pin
B Locking Nut
C Spool
D Cap
E Filament Guide

Fig 1 Diagram of vernier calipers modified for measurement of convex curves.

The filament was attached to the spool by a knot anchored in a small hole drilled through the top flange. The filament could have been tied around the spool. Approximately 15 centimeters of filament were wrapped on the spool. The filament was then passed through the guide tubes and knotted so that the knot was anchored against the second guide tube.

Application

The calipers may be used in the normal manner by either placing the object to be measured within the jaws from the side or by using the inside diameter prongs as determined by the shape of the object to prevent the diameter of the filament from interfering with accurate measurement. The caliper slide lock screw may be tightened to prevent slippage. The outside diameter prongs are then applied to the subject while the filament is allowed to unwind from the spool. When a snug contour is achieved, the locking nut is tightened against the spool. The straight line distance is recorded before the calipers are spread to measure the distance along the curve. Once practiced, the process can be accomplished without awkward handling of either the specimen or the calipers.

The modified calipers can also be used to measure the circumference of small round objects as well as the contours of convex curves. Circumference has been measured on the eggs of marine turtles.

Accuracy

The accuracy of the basic calipers is not altered by this modification. However, three factors which affect the accuracy of measurement along the curve are evident: the elasticity of the filament, the distance over which this stretch operates and the tension applied. The selection of a filament is incomplete. Monofilament fishing line, multi-strand twisted nylon thread, dental floss and surgical suture have been tried. Braided silk surgical suture (2.5 metric or 2/0 B.P.C.) have proved to stretch the least: 0.01 cm at 6.60 cm distance during 100 tests. The placement of the spool assembly and anchor close to the tips of the prongs helps to reduce the stretch-error in the measurement.

The tension of the filament over

the contour of the curve remains the greatest source of error. With practice, an operator can maintain the same tension over the curve and during linear measurement.

Repeated measurements of inanimate and animate objects have produced a consistent error or less than 0.5%.

Summary

The modified vernier calipers allow measurement of convex curves with convenience and accuracy.

Acknowledgements

I should like to thank Mr. M. Road of the University of New England who built the prototype from a crude drawing. I also wish to thank Mr. C. J. Limpus of Queensland National Parks and Wildlife Service and Dr. R. Winokur of the University of New England for reading the manuscript.

A Simple Trap for Basking Turtles

Specimen capture has always been a major problem when studying turtles. The following is a description of a basking trap that has been used successfully to capture Graptemys geographica.

Several basking trap designs using ramps or treadles have been used by various authors (Cagle, 1950; Ream and Ream, 1966; Clark and Gibbons, 1969). These designs are complex, expensive to purchase or time-consuming to construct and are not easily transportable. All are designed to prevent captured turtles from escaping. Sexton (1959) used a floating square frame of 2" x 4" basking boards surrounding a chicken wire net into which the turtles fell after basking. The probability of any one turtle being captured is only 50%.

The new design is inexpensive and easy to construct. It consists of a floating square frame of 1" x 1" or 1" x 2" boards supporting a net (Fig. 1). This design used small mesh nylon netting of the type used to protect crops from birds. The net is stapled to the frame and submerged by a few small stones. A floating basking board made from a length of 2" x 10" lumber is attached to the frame by wire passed through fence staples. The whole assembly is held in position by anchors at both ends.

The trap is placed in a favourable location. Turtles climb out on the basking board, usually from the ends. Upon arrival of the collector, the turtles drop into the net and are easily removed by boat or by wading. One advantage of the design is that the traps do not have to be tended regularly; turtles can easily surface and escape by climbing over the frame. Because of the un-trap-like nature of the design, turtles readily use the traps as basking sites. The traps can be easily moved to accommodate changing water levels or movements in turtle populations.

Another advantage is that these traps can be constructed from almost any scrap or leftover material. Any available type of lumber or netting would be suitable. Bricks or scrap metal can be used as anchors. Traps can be easily transported by automobile or boat in a partially assembled state.

These traps have been used with great success in an ongoing study of Graptemys geographica. One trap on one occasion caught eleven individuals. All size classes of map turtles have been caught and there is no apparent bias in the sex ratio of trapped turtles. The traps used measure approximately 90 cm on a side; for larger species, greater dimensions may be desirable.

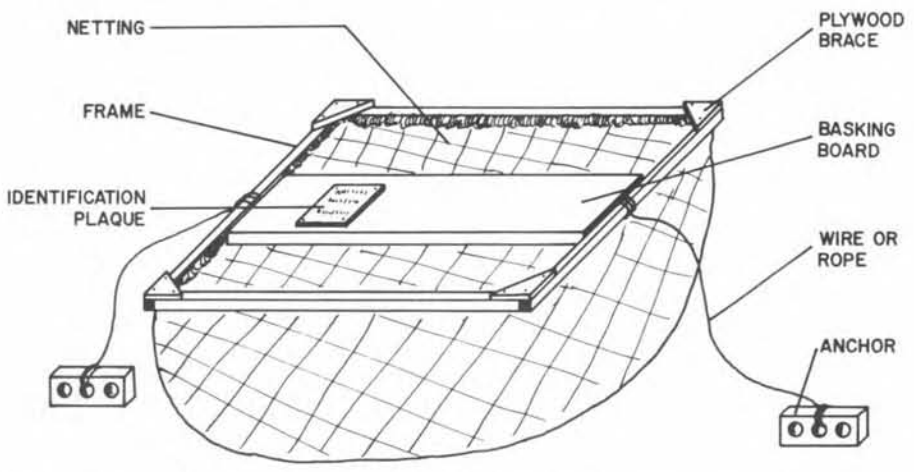

Figure 1. Diagram of the new design of turtle trap.

SSAR Business

Minutes -- Business Meeting 2 June 1978

The SSAR General Business meeting was convened by Joseph T. Collins, Chairman; those assembled did not constitute a quorum of the Society. Collins reviewed the actions taken by the Board at their meeting on Wednesday, May 31:

It was decided that, due to a backlog of species accounts, the Society would publish 25 species accounts for the Catalogue of American Amphibians and Reptiles during 1979. There will be no additional cost to subscribers. Also, on an experimental basis, the address of the senior author will be included in citations published in the Current Literature section of Herp. Review.

It was reported that the Committee on Translations had a number of papers available. A list of available papers will be advertised in a future issue of Herp. Review. This is a new program that can provide a valuable service. All members are urged to take advantage of this service.

Collins reported that the Committee on Scientific and Common Names had completed its task and that the Committee's report would be published as Herpetological Circular No. 7 during the forthcoming year. It will be distributed gratis to all members.

The Legislative Alert Committee has developed an extensive network

for collecting information about pending legislation and/or regulations that affect our community at both the national and state levels. The network is designed to provide rapid responses from qualified professionals on federal and state issues that affect herpetology. The Committee has provided numerous comments on proposed listings of herps.

Collins presented the recommended slate of candidates for the elective offices of the Society for 1979: Chairperson--James E. Huheey and Robert G. Webb; Secretary--Stephen R. Edwards; Treasurer--Henri C. Seibert; Directors (two to be selected for the Class of 1981)--Roger Conant, Sheldon Guttman, Robert Jaeger, Edward Moll, and Samuel S. Sweet. Kirkland Jones moved (and it was seconded) to accept the slate of candidates as presented by the Nominating Committee. All present voted unanimous support for the slate of candidates.

Collins announced that the second annual Regional Herpetological Society Conference had been scheduled during the Tempe meetings. Preparations had been under the direction of Tom Johnson. Based on preregistration, it appeared that this conference would be as successful as the first.

Collins announced that the Board has approved, in principle, a Grants-In-Herpetology program that would be initiated in January 1979. Further, any awards made under this program would be announced at the Knoxville meeting. It was reported that over the past few years considerable funds had accumulated in the Conservation Fund ostensibly to be used for the purchase of land to insure the survival of endangered species. To date, this fund had been used only once; a contribution to the Organization of Tropical States to purchase land in Costa Rica. Those in attendance were asked if it would not be appropriate to use these funds to support the Grants-In-Herpetology program. In response, following considerable discussion, Craig Nelson moved (John Brody seconded) to use those funds for continuing the conservation grant aspect of the Grants-In-Herpetology program. All present voted in the affirmative except one.

In subsequent discussion concerning the impact of such votes on the Board, Craig Nelson moved (Ralph Axtell seconded) to recommend that the Board consider modifying the bylaws of the Society so that those present, and voting at an announced business meeting, at the annual meeting of the Society, would constitute a quorum. Of those present, only two responded in the negative.

It was announced that the budget for 1979 was set at $48,000.

Pursuant to Article IX of the bylaws, Collins read a proposed amendment to the bylaws that would change the title "Chairman" to "President" in the bylaws. Eldon Romnie moved (Jim Knight seconded) to accept the recommendation and to submit the proposed amendment to the members on the election ballot that would be circulated following the meeting.

Collins adjourned the meeting thanking all those that participated for their interest and support.

Respectfully submitted,

Stephen R. Edwards

Report of the SSAR Committee on Common and Scientific Names for 1978

This report is the first of annual up-dates to be prepared by the SSAR Committee on Common and Scientific Names for North American Amphibians and Reptiles (north of Mexico). This report (and future reports) is compiled to fulfill the charge to our committee to keep the herpetological community informed of published taxonomic shifts and new descriptions, and to propose new common names brought about by same. In addition, this first report will permit us to point out typographical errors, inadvertant omissions, and a few outright errors that appeared in "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (1978).

The proposed changes and corrections listed below are in order as they appear in our Common and Scientific Names list.

PAGE 3, table 1: For Frogs and Toads, 80 species should read 81, and the species total should read 455, not 454.

PAGE 8, line 14: P. n. hubrichti should be called "Peaks of Otter Salamander," not "Thunder Ridge Salamander." P. n. hubrichti is not found on Thunder Ridge (Richard Highton, pers. comm.).

PAGE 13, line 3: malanota should read melanota.

PAGE 13, line 18: Rhinophrynus dorsalis should be "Mexican Burrowing Toad," not "Mexican Burrowing Frog."

PAGE 16, line 7-8: Iverson (1978) has proposed that the subspecies of Kinosternon bauri not be recognized.

PAGE 29, line 35: Lampropeltis triangulum celaenops should be "New Mexico Milk Snake," not "Mexico Milk Snake."

PAGE 30, line 2: Williams (1978) has proposed that Lampropeltis triangulum temporalis not be recognized as a valid race.

PAGE 30, line 35: lineatus should read lineatulus.

PAGE 35, line 30: rufipunctata should read rufipunctatus.

PAGE 36, line 1: Webb (1966) proposed Thamnophis sirtalis dorsalis as a replacement for T. s. ornata. The latter should be deleted from the list. The common name remains unchanged.

PAGE 36, line 5: semifasciata should read semifasciatus.

Those individuals wishing to keep their lists current should so note the above changes. We are indebted to George R. Pisani, Richard Highton, and Douglas A. Rossman for bringing some of these changes to our attention.

Mexican Herpetological Literature, Automation, and the Future

SYNOPSIS OF THE HERPETOFAUNA OF MEXICO. Volume IV. Source Analysis and Index to Mexican Amphibians. Hobart M. Smith and Rozella B. Smith. 1976. John Johnson, R.D. 2, North Bennington, Vermont 05257. 1976. 260 pp., cloth bound, $12.50.

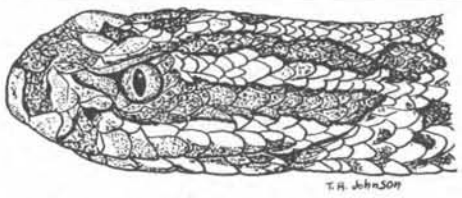
A completely cross-referenced index to the literature on the herpetofauna of Mexico through 1973! Yes, it has been finished. The publication of volume 4 of the "Synopsis of the Herpetofauna of Mexico" provides biologists with a literature search system that is unparalleled in our field. Volumes I and II contain the literature references, and volumes III and IV comprise indices to the literature on reptiles and amphibians respectively. These four volumes are the results of a unique combination of resources--Hobart Smith's unequalled knowledge of the literature on the Mexican herpetofauna and Rozella Smith's uncanny abilities with electronic data retrieval systems.

Following a general introduction, the volume is conveniently divided into three major sections corresponding to the taxonomic groups of amphibians--frogs, salamanders, and caecilians. Each section contains an introduction, primary index, synonym list, species combination list, subspecies combination list, state list, and valid name list. At first glance, the pages seem to be filled with an incomprehensible jumble of names and numbers, but upon reading the simple instructions in the introduction it is possible to obtain readily all of the literature references (contained in volumes II and III) to a given species no matter what name combination or synonym was used in the references. By a somewhat more laborious task, one can obtain the literature references pertaining to a given state in Mexico. The only more rapid access to the literature would be to have a remote terminal access to Smith's computer file.

For those of us who have spent hours pawing through the Zoological Record and recent issues of journals and museum publications in the agonizing effort of obtaining a bibliography on a given genus or species, the first four volumes of the "synopsis" are analogous to a pair of crutches to a double amputee. The prodigious task of indexing can only be inferred from the number of bibliographic items (1457 for frogs, 961 for salamanders, and 151 for caecilians) giving 15,817 index entries. (The numbers for reptiles in volume III are much higher.)

The computerization of the bibliography and index has permitted the acquisition of certain kinds of data not otherwise available. Thus, as in the preceding volumes, the authors have provided chronologies of authors and taxa and various other kinds of data, such as citation frequencies. Although these data included in the introduction to each major group are superfluous to the index, they do provide some interesting insights into the literature on Mexican herpetology. As examples, 61 authors are responsible for naming the 202 taxa of Mexican anurans; Taylor named 35, Cope 15, and Boulenger only 8. I was amazed to find that the greatest number of works per author on Mexican anurans is 52 and that that number is shared by Hobard M. Smith, Edward H. Taylor and me!

The promulgation of electronic data processing systems and the availability of diverse kinds of "software" provide biologists and bibliographers with powerful tools to store, index, analyze, and retrieve information. The Smith's endeavors, although modern to the thinking of most of us, are only a first step in the forthcoming automation revolution.



Although most biologists are aware of the benefits of computerization of research data, perusal of most any journal, especially Systematic Zoology and Ecology, reveals a variety of results ranging from numerical techniques in systematics to ecological modeling. But two fields are only on the threshold of automation--data management (with its attendant literature) and publication. Retrieval of electronically processed data based on literature, specimens, characters, etc. has a variety of applications. Hall (1971) and Morse, Peters, and Hammel (1971) demonstrated computer-generated keys to the identification of taxa. Sala and Simmons (1977) have proposed a computerized universal taxonomic checklist. Electronic data processing of museum collections is in process in several museums. A variety of systems are available that permit rapid retrieval of data in diverse categories; see Neuner (1976) for details of one widely used system. It is now possible to have computer-generated distribution maps, and by using overlays from satellite imagery, one can determine relationships between distribution patterns and various environmental factors, such as soil moisture, vegetation type, and vegetation cover.

Computer-based technological advances are revolutionizing the printing industry; soon, conventional linotype machines will be historical artifacts. Manuscripts can be

composed on a remote terminal, stored in a computer, edited, and output into a photo composition system--all much faster and less expensive than conventional techniques. Editorial processing centers will eliminate much of the time-consuming editorial chores, while still preserving the integrity of individual journals (Rhodes and Bamford, 1976). But in the near future, publication as we know it today probably will be a thing of the past for the most part. Journals will consist of abstracts (with key words noted for bibliographic indexing). The text of the paper will be on file in a data bank; it will be available to interested researchers upon request, perhaps through a remote terminal in your office. Or, a whole series of papers or even a complete "issue" of a journal will be available on videotape and the illustrations in the form of stereomicrographs (Capital Systems, 1966). In the foreseeable future in scientists' offices, computer terminals will be as common as (and more frequently used than) telephones are today.

So, what might 1984 be like for the biologist interested in Mexican herpetology. Let us review the procedure a few years hence. Dr. Future is a curator of a large herpetological collection. He has received a collection of amphibians from a colleague in Mexico. Sitting at his remote terminal, he calls up the Mexican frog key in the computer. Series of questions flash on the screen and he quickly checks the characters on his specimens until he has passed through the key and received identifications of his species one by one, save for one identified only to genus--its combination of characters differing from all others stored in the file. The need for investigation is obvious. A check of the extensive holdings of the genus in the collection reveals that all known species are well-represented and none has the characters of the newly acquired specimens. A literature search of an updated index to the literature on the Mexican herpetofauna is printed out by the terminal while Dr. Future is enjoying lunch. A perusal of pertinent literature reveals no records of such frogs.

The search cannot end there. Again residing at his terminal he calls up the data banks of all major museums in the country and within a few minutes has a list of all specimens, their catalogue numbers and localities. None is from the area from whence his new specimens came. Standard measurements are taken by means of electronic measuring devices and optical scanning and input directly into the computer, which upon demand produces standard statistics and graphs. Optical scanning produces a computerized image. Geo-

graphic coordinates, together with conventional catalogue data are entered into the system. The coordinates, as well as those of localities for the specimens from all of the museums are entered into a mapping program, which produces an up-to-date map of the distributions of the species in the genus.

The second day is devoted to "writing" on the terminal; a text editing program allows for rapid "rewriting." The final touches include the insertion of the "figures" and having the computer add the literature cited. Satisfied that the "manuscript" is ready for the editor, he has it put into the computer. The editor receives a call to retrieve the manuscript. Minutes later he is perusing it and decides upon two appropriate reviewers, whom he instructs by phone to call up the manuscript on their terminals. Using text editing systems, each reviewer makes changes and corrections; these are retrieved by the editor, who reviews the changes and calls the author. Dr. Future incorporates the changes and "sends" the manuscript back to the editor, who upon checking the abstract and key words puts the manuscript onto the magnetic tape containing all manuscripts for next month's issue.

Upon processing all manuscripts for the forthcoming issue, the editor informs the printer that he may retrieve the manuscripts for the next issue from the computer. Photocomposition of the titles and abstracts is completed rapidly; all titles and key words are entered into the bibliographic bank, and all manuscripts are coded and stored in the manuscript bank. In a few days all subscribers to the journal are reading the abstract of a paper describing a new species of frog received by Dr. Future only two months before. The few people who are really interested in these frogs obtain copies of the entire paper--output by their remote terminals. Impossible? Unlikely? Wait and see.

Are there pitfalls to overcome? Yes, but these are primarily the same ones that we face today and most, if not all, result from human error. Although the Smiths have cross-indexed all name combinations, they cannot substantiate the correctness of the identifications given in the references. A curator's specimens might be a well-known Asian frog bearing incorrect locality data. After all, it was only a few years ago that a new genus of hylid frog was named from South America only to be pointed out subsequently that the name was based on a specimen of a common African species! Whether we produce manuscripts with a crow-quill pen or with a computer, we will make mistakes, for we humans are fallible.

Probably the "synopsis" contains many errors--some by the authors and many more emanating from the references themselves. Nonetheless, the four bibliographic volumes of Mexican herpetology set a standard and a precedent; moreover they provide us with a giant step towards the future. It behooves members of the herpetological community to extend their gratitude to Hobart and Rozella Smith for their dedication, perserverance, and leadership.

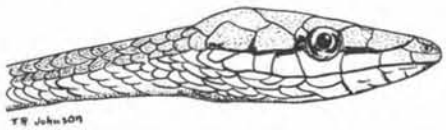
TOXICOLOGY AND PHARMACOLOGY OF VENOMS FROM POISONOUS SNAKES, by J. H. Brown. C. C. Thomas, Springfield. 1973. xiv + 184 pp. ill. paper.

VENOMS: CHEMISTRY AND MOLECULAR BIOLOGY, by A. T. Tu. J. Wiley & Sons, N. Y. x + 559 pp. ill. $34.50.

SNAKES AND SNAKEBITE: VENOMOUS SNAKES AND MANAGEMENT OF SNAKEBITE IN SOUTHERN AFRICA, by J. Visser and D. S. Chapman. Purness, Johannesburg. 1978. 152 pp., ill. (obtainable from Purnell Book Services, P. O. Box 10021, Johannesburg 2000, S. Africa. $11.50 + .50 postage).



Although all three books deal with venom from snakes, they differ

in many respects in their approach to the subject. This brief review is from the point of view of a herpetologist and not that of a clinician or molecular biologist. Obviously, the Visser and Chapman book is limited geographically yet it provides more information of herpetological interest such as the structure of fangs, of venom glands, the biting behaviors of snakes, etc. Each South African species of poisonous snake is illustrated by a color plate. The clinical symptoms of snakebite are clearly described and correct and incorrect treatments critically compared. Range maps, bibliography and glossary are included.

Brown's book is worldwide in scope and concentrates more on the comparative toxicity of venoms. There are chapters on pharmacology, symptomatology and treatment, mortality rates, and a long table listing all the known poisonous snakes (including subspecies) and their distribution. Unfortunately, of the many color plates, most are of poor quality (one even upside down!). But if you want an answer to the oft-raised question, which is (are) the most dangerous (poisonous) snake(s) in the world, this is by far the best place to find the information.

As the subtitle indicates, Tu's book analyses the chemical construction of venoms as currently known from all those studies and it also describes in detail the effects of envenomation on systems and tissues of the body, both clinical and experimental. This is by far the most technical of the three books and probably the least interesting to the general herpetologist, but it contains the most detailed and comprehensive information on venoms. If anyone harbors the idea that snake venoms are simple secretions, a cursory examination of this text will quickly dispel the notion. Venoms are unbelievably complex, and each species of snake apparently has its own unique combination of substances. The venoms of the Gila monster, of spiders and hymenopterans are also included in this text. The bibliography is exhaustive but the editing and proofreading of the text material has been rather casual. To those who may be concerned about what to do in case of envenomation, I recommend Visser and Chapman, which was written by a herpetologist and a surgeon and harmonizes the two fields to best advantage.

HENRI C. SEIBERT, Department of Zoology, Ohio University, Athens, Ohio 45701.

FLORIDA FROG CALLS: A GUIDE TO COMMONLY HEARD FROGS AND TOADS. Produced by Richard A. Bradley, 1978. LP monaural record. Available from: Florida State Museum Collector's Shop, Univ. of Florida, Gainesville 32611. Price $4.00 + .50 postage -- 4% sales tax to Florida addresses.

This delightful album provides listeners with samples of the breeding calls of 20 species of Florida anurans, plus rain calls of several. The taxa presented represent the bulk of Florida's anurans, and certainly include all that would be "...commonly heard...." Individual calls and seasonal choruses are recorded with excellent fidelity, and background noise (where at all present) is at a bare minimum. Linda Becker's pleasant, well modulated voice provides nice narration, and all-in-all, the disc is a fine companion piece to Cornell University's Voices in the Night (soon to be re-issued). The record provides interesting listening, and would be a useful teaching tool (anuran isolating mechanisms) for herpetologists lacking access to recordings of varied anurans.

I could wish for a couple of more Rana clamitans notes (only one distinct call is used--room exists on the side for others), and Archie Carr's jacket text rambles too much. Nevertheless, as I said before, it's a fine album and I recommend it highly.

GEORGE R. PISANI, Department of Biology, University of Kansas, Lawrence, Kansas 66045.

THE HANDBOOK OF AMPHIBIANS AND REPTILES OF U.S.S.R. by A. Bannikov, I. Darevsky, V. Lsehenko, A. Rustamov and N. Seherback, 416 pp., illustrations, maps. Published by Government Printing, Moscow, 1977.

This book is suitable for scientific identification of all known specimens of the herpetofauna of U.S.S.R., including short notes about the biology of all species and a bibliography. For any species, the authors note synonyms, terra types and named subspecies, but the identification keys extend only to species level. All species are illustrated by drawings, including 32 colour plates. Ranges of species are shown on 135 maps. This handbook is a more detailed and scientific version of the earlier, popular handbook "Amphibians and Reptilians of U.S.S.R." by A. Bannikov, I. Darevsky, and A. Rustamove (Moscow, 1971, 304 pp.) and the more recent version of the old classic work "Handbook of Amphibians and Reptilians of U.S.S.R." by P. Terentev and S. Chernov (Moscow, 1949) that describes 178 species in the herpetofauna of U.S.S.R., and contains new Russian literature, especially in systematics and zoogeography. The maps show between 90-100% of known localities according to collections of the major Russian museums, and incorporate the previously unpublished field notes from over 45 noted Soviet herpetologists. Another academic handbook of herpetofauna of U.S.S.R. is not planned for publication in the near future. Therefore, this handbook may be useful for professional herpetologists, students, or amateurs for some years into the future as the best identification guide of the Soviet herpetofauna, as well as a source of information about herpetological ecology and literature. The colour plates by Knodakov are based on his earlier plates in "Handbook of Amphibians and Reptilians of U.S.S.R." (Moscow, 1971), but other illustrations and maps are new. This handbook includes modern research by I. Darevsky on caucasian rock lizards, by N. Scherback on Eremias and by other workers.

THE PARASITE WORMS OF REPTILIANS OF U.S.S.R. by V. P. Sharpilo. Published by the Academy of Sciences, Ukrainian SSR, Institute of Zoology, Kiev, U.S.S.R., 1976, 288 pp., illustrated.

This monograph is based on the author's helminthological research between 1958 and 1974. The author's personal collection of material plus that of other researchers including the parasitic worm collection of Professor K. Skrjabin is discussed. The worms were collected by V. Sharpilo from 3772 reptilians collected from over 180 localities of U.S.S.R. Also included are samples from 98 reptilians from Mongolia, Bulgaria and some materials from China and Korea. Contained are reptiles of 27 species from other collections and 93 species from the author's research - over 140 (sic) species. The total number of newly described parasite species in this work is over 60. This monograph is highly technical, and may be of interest for professionals only, especially for specialists in helminthology. It will also be useful for veterinarians, and specialists in reptilian diseases. Some information from this book may be useful for ecological studies of reptiles. This book is the first monograph in this field in U.S.S.R., and the bibliography, identification keys, and figures of parasites should be valuable in the study of reptile diseases. Over 200 species of parasites are described in this book including known information about their life cycles and biology. It incorporates new material published about parasites of reptilians in Kazachstan, Central Asia, the Far East part of U.S.S.R., and eastern Europe (Bulgaria, Hungary, East Germany, Czechoslovakia) thus providing a book of the highest

currency for European specialists too.

THE CATALOGUE OF AFRICAN DESERT LIZARDS by N. Scherback, Academy of Science of Ukrainian SSR, Institute of Zoology, Kiev. 1975.

This monograph is based on the literature and is related to an earlier work by Scherback, The Palearctic Desert Lizards. The catalogue contains diagnoses of African specimens, synonyms, range maps, names of collection localities, and a bibliography inclusive to 1 January 1974. The author adheres to Boulenger's taxonomy, and generally uses the conventional genera. It differs in such genera as Pseuderemias, Lampreremias, Mesalina, and Taeniereremias, together containing 32 species that belong to subfamily Eremiaidae. The African center of species evolution is considered independent from other centers.

This small paperbound book may be interesting to specialists in African herpetology, but a small circulation (500 copies) limits easy accessibility. Only major scientific libraries will have this book and may supply material from it for those desiring such.

This book is now out of print.

GEORGE MAMONOV, 252056 Kiev 59, Artema Street 74-3, U.S.S.R.

Herpetological Husbandry

GROWTH OF THE COBRA NAJA NAJA (SERPENTES, ELAPIDAE)

Studies on growth of certain species of snakes have been reported (Carpenter, 1952; Fitch, 1960; Wharton, 1966, Dmi'el, 1967; and others), but information is scant on the growth of the cobra Naja naja. On 28 November 1973, one N. naja hybrid hatched at the Fort Worth Zoo. Another hatched on 29 November and three on 1 December 1973 (Campbell and Quinn, 1975). Their parents were intergrade N. n. naja X N. n. kaouthia. Weights to the nearest 0.1 g and total lengths to the nearest mm were periodically recorded on all snakes (Quinn and Jones, 1974). One cobra did not eat and died on 27 February 1974, but the others were weighed and measured until 10 May 1976. The snakes were kept at ambient temperatures between 24° and 30° C with occasional readings as high as 35° C during summer months. They were housed in well ventilated fiberglass enclosures 75 x 30 x 30 cm with glass fronts. All snakes refused food for the first month. In January 1974, two began eating young mice, one began eating snakes (Coluber constrictor), and in February the others also began eating snakes (Thamnophis sp.). All cobras began eating mice by March 1974. By June 1974, all snakes were eating mice each week. All snakes shed for the first time at age 9 days.

Other authors reported total lengths of hatchling Naja naja from 228-360 mm (Table 1); others were 295-337 mm ($\bar{x}$ = 308 ± 1.83 mm). Petzold (1968) reported the weights of hatchling N. n. atra from 13.8-16.0 g. ($\bar{x}$ = 15.3 ± .14 g). The weights of our snakes were 18.0-20.4 g ($\bar{x}$ = 19.24 ± .49 g). The maximum total length reported for this species is 7 feet (2,133.6 mm) (Smith, 1943); our longest individual measured 1,230 mm ($\bar{x}$ = 1052 ± 4.89 mm) at age 29 months.

Table 1. Total lengths of hatchling Naja naja

Length (mm) / Subspecies / Authority
240-360 / N.n. oxiana / Smith, 1943
254 / unknown/ Miller, 1970
270-295 ($\bar{x}$=285.5±.17) / N.n. atra / Petzold, 1968
228-286 / N.n. naja / Wall, 1922
340-360 / N.n. kaouthia / Schweizer, 1952
250-300 / N.n. naja / Deraniyagala, 1955

Specific growth rates ("G" or "g") were calculated by using the following equation:

$$G = 100g = 100 \frac{\log YT - \log Yt,}{T-t}$$

where YT and Yt are the dimensions of the snakes recorded at times T and T and G is expressed as per cent unit time (Medaware, 1945; Brown, 1957). The general trend of growth was to decrease in rate as time progressed (Fig. 1). This agrees with observations made on Naja naja by Smith (1943). Wall (1921) reported that young cobras measuring 304.8 mm in length in July averaged 762 mm by the following July and 1,473.2 mm by the end of the fourth year. Assuming that these cobras were hatchlings in July, this closely agrees with our data for the first year of growth (Fig. 2), but we further show (Fig. 1) that their peak length specific growth rate was during their first month of life and that their peak weight specific growth rate was at age 11 months. Our data also show that at age 18 months the cobras were continuing to increase in length (Figs. 1 and 2). There also was a cyclic peak in length specific growth rate approximately each 3 1/2 - 4 months for the first year of growth. Weight peaks were 4-5 months apart during the 18 months that weights were recorded. There appeared to be no correlation between specific-weight growth rate and specific-length growth rate. The cyclic fluctuations of weight and length specific growth rates were apparently not caused by variations in temperature or food intake, so they may have been intrinsic in nature. There was little similarity between the specific-growth rates in our cobras and those of the colubrid Spalerosophis cliffordi (Dmi'el, 1967). When we plotted length and weight against time (Fig. 2), we found length growth was quite similar to that of Spalerosophis cliffordi raised in captivity under artificial heating (Dmi'el, 1967) and somewhat similar to the crotalids Agkistrodon piscivorus (Wharton, 1966), Agkistrodon contortrix (Fitch, 1960), and others that were studied in the wild. The weight growth of our cobras was slower than that reported for N. n. atra which had a mean weight of 15.3 ± .14 g upon hatching and reached a mean weight of 122.6 ± 8.92 g at age 11 months (Petzold, 1968). The mean weight of our cobras at hatching was 19.2 ± 2.49 g and 84.9 ± 3.67 g at age 11 months.

Our snake that refused to eat and died illustrated a length specific growth rate of 13.63% ($\bar{x}$ = 17.85%) during December 1973, and 1.40% ($\bar{x}$ = 3.52%) during January 1974. Its weight specific growth rate was -17.56% ($\bar{x}$ = 16.95%) during December 1973, and -18.09% ($\bar{x}$ = 1.86%) for January 1974. Thus, while this snake remained close to the mean in length specific growth rate, its weight specific growth rate was far below the mean.

We wish to thank the Fort Worth and Houston Zoos for making this study possible. Gary W. Ferguson critically reviewed the original manuscript.

A Restraining Apparatus for Unanesthetized Snakes

The restraint of snakes has been a problem which has vexed the researcher requiring immobile subjects. Most often the problem has been dealt with by the use of anaesthesia (Brazenor and Kaye, 1975; Karlstrom and Cook, 1955; Betz, 1962; Hackenbrock and Finster, 1963; and Wang, Kubie and Halpern, 1977). However, anaesthesia cannot be used when an alert subject is required, or when the anesthetic might have an effect on the variable being studied. For these situations, mechanical restraint is required. Luck and Keeler (1929) described a "trough" in which their specimens could be securely strapped. Johansen (1959) used a flexible polyvinyl tube with removable perforated stoppers on each end to allow entry of the snakes and to allow air intake. Sutherland and Hampton (1961) used a similar tube; however, instead of using rubber stoppers to prevent escape, they taped the snake's tail to a flat projection at the end of the tube. McDonald (1964) described what is probably the simplest method of immobilizing snakes. He tapes them bodily to round sticks which were slightly greater in diameter than the snake.

These methods of restraint all have certain drawbacks. Tubes limit access to the specimen, and because the tube can never fit any specimen snugly at all points on the body, it allows a certain amount of movement to occur. Taping snakes to rods may damage their skins. This is especially troublesome prior to ecdysis. In addition, all these forms of restraint are not flexible in terms of the size of the snake which any single restraint can handle. If more than one specimen is to be studied, the snakes either have to be closely matched by body diameter, or a different restraint apparatus used for each odd-sized specimen.

In an attempt to circumvent these various problems, the apparatus shown below was designed. It consists of two 36 inch by 2 inch by 1 inch painted boards joined to produce an L-shaped frame which, on the interior of the L, is two inches wide along the horizontal plane and one inch tall along the vertical. Beginning six inches from either end of the vertical board, and extending for 24 inches, is a slot 1/4 of an inch high, flush on its lower edge with the horizontal board. Along the rear surface of the vertical board, and just above the slot, is attached a twenty-four inch strip of coarse velcro (1). On the horizontal board, twelve six-inch long strips of soft velcro are attached soft side down at one-inch intervals perpendicular

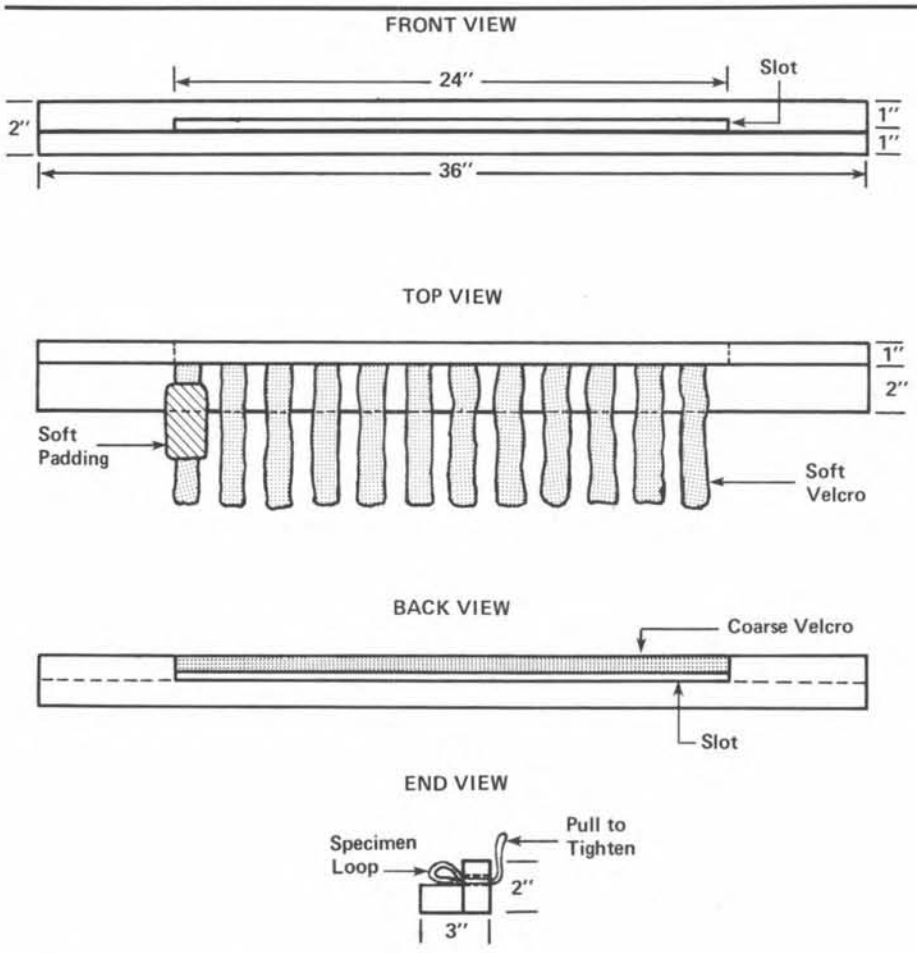

Figure 1. A restraining apparatus for unanesthetized snakes.

to the long axis of the device. These are attached as near the vertical board as possible. To prevent the snake from straining backwards against the velcro and inflicting small lacerations on the back of the head and neck, a soft pad is attached to the first strip of soft velcro.

Strapping a snake into the apparatus is done by laying it on the horizontal board so that the velcro strips are flat beneath the specimen and will extend out from under it. The head of the snake is held so that it is just forward of the padded strip of velcro. This strip is then pulled across the posterior portion of the snake's head, slipped through the slot in the vertical board, drawn firm, and then pressed against the strip of coarse velcro on the rear of the vertical board. This process is repeated with the other strips, beginning with those furthest forward. Care should be taken that the velcro is firm, but not so tight as to impede circulation or respiration. If care is taken when placing the snake in the apparatus, neither escape nor injury is probable.

Our use of this apparatus has, so far, been limited to the study of intermittent reinforcement of tongue flicks in Nerodia rhombifera and Elaphe guttata emoryi. However, the device has the potential to be useful in various types of research. The instrument has shown itself to be adaptable to a wide range of sizes with the two species used. Species with a less distinct head, or species which are very small, might prove troublesome. However, with proper modification, this device should be able to accommodate a large variety of species and various sized specimens.

An Observation of Double Clutch Production by Elaphe obsoleta in Captivity

Fitch (1970) hypothesizes that reports of late summer egg clutches of the colubrid snake Elaphe obsoleta, as reported in the literature, may represent second clutches by the same female. In summarizing the literature, Fitch finds the following colubrid snakes confirmed as reproducing twice in the same year: Boeadon lineatus, Pituophis, Ptyas, Spalerosophis, Thamnophis, and Xenochrophis vittata. He also suggests double clutches in other species.

The author received a male Elaphe o. obsoleta 1 January 1975 (captive bred and hatched 19 August 1974) and a female Elaphe obsoleta quadrivittata 19 December 1975 (captive bred and hatched 1972). The pair has been housed together consistently. A single clutch consisting of 10 eggs was deposited 22 April 1976; however, only one of the eggs proved fertile and hatched 11 July after an 80 day incubation period. In late April and early of May 1977 courtship activity was observed. As expected, a clutch of 13 eggs were deposited 19 June. Unexpectedly, however, another clutch of 10 eggs was deposited 17 August. Hatching and viability of data are shown in Table 1. As you can see, the second, smaller clutch had the higher fertility rate though more young died before hatching. Egg size was slightly larger in the second clutch while incubation period was insignificantly shorter. While both adult snakes fall within the size parameters given by Conant (1975), the

female seems unusually small at about four feet.

Table 1

Date of Clutch Deposit	19 June 1977	17 August 1977
Average Egg Size	34 x 16mm	39 x 18mm
Clutch Size	13	10
Fertile	9	7
Infertile	2	0
Number Dead	2	3
"Net" Clutch Size	84.6%	100%
Date of Hatching	8/25-29	10/19-21
Incubation Period (Days)	67-71	63-65

Elapsed time between clutches: 59 days

Legislative Alert

Legislative News

Since the last issue, the following rulemaking actions have taken place --

Proposed regulations:

1) The U.S. Fish and Wildlife Service proposed the San Marcos salamander (Eurycea nana) for Threatened status and its range (Hays County, Texas) as Critical Habitat (F. R., Vol. 43, No. 136, 14 Jul 78). Public comment period closed 15 September 1978.

2) The U.S. Fish and Wildlife Service proposed the Beaver Dam Slope population (Washington County, Utah) for Endangered status and its range as Critical Habitat (F. R., Vol. 43, No. 164, 23 Aug 78). Public comment period closed 23 October 1978.

Final regulations:

The U.S. Fish and Wildlife Service has determined the New Mexican ridge-nosed rattlesnake (Crotalus willardi obscurus) to be a Threatened species, and its known range in southwestern New Mexico has been designated as Critical Habitat (F. R., Vol. 43, No. 151, 4 Aug 78).

NOTICE: A meeting of the Conference of the Parties to the Convention on International Trade in Endangered Species of Wild Fauna and Flora is scheduled for March 19-31, 1979 in San Jose, Costa Rica. Rule changes regarding CITES-listed organisms are expected. ●

New Illinois Regulation

Collecting snakes from the Murphysboro dens vicinity in the Little Grand Canyon/Horseshoe Bluff/Chalk Bluff area of Jackson County, Illinois is now prohibited except under permit from the District Ranger, Murphysboro Ranger District, Shawnee National Forest. The general area lies between the Muddy River and, to the east, Cedar Creek, with Swallow Rock to the north and Lookout Rock south. Maps of the precise area are available from the District Ranger. ●

California Collectors Cited

Two California men were fined $672.00 each for collecting reptiles in the Huachuca Mountains, near Sierra Vista, Arizona. They were cited for three violations. One was for collecting without an Arizona hunting license, one for possessing non-native venomous reptiles (S. Pacific rattlesnakes) and the third for transporting non-native venomous reptiles. Each violation carries a fine of $224.00.

Leonard Contreras of El Segundo, Calif., and Daniel Havens of Arroyo Grande, Calif., were asking local residents about places to collect Ridge-nosed Rattlesnakes and local residents reported them to the Arizona Game and Fish officials via the newly installed toll free "Hot Line", according to Phil Cosner, Assistant Director of the Game and Fish Department. In addition to the fines, the specimens and collecting equipment were confiscated.

...from Arizona Herp. Association Newsletter, 8(11): 5 (October 1978). ●

Regional Society News

New Herp Society

The North Carolina Herpetological Society was formed in May 1978 and held its initial organizational meeting at the NC State Museum of Natural History. The NCHS issued its first newsletter (Volume 1, number 1) entitled "NC Herps" in August 1978. Dave Stephan has been elected chairperson of the NCHS steering committee, and Pat Ashton will serve as secretary. Individuals wishing to join or learn more about the NCHS should contact: Ms. Pat Ashton, NC State Museum of Natural History, P. O. Box 27647, Raleigh, North Carolina 27611. ●

Regional Herp Society Omitted

The SSAR Directory of Regional Herpetological Societies which appeared in Herp. Review, 9(3): 105-106, was incomplete. Inadvertantly omitted from the directory was the PALM BEACH COUNTY HERPETOLOGICAL SOCIETY, 4422 Birdwood Street, Palm Beach Gardens, Florida 33410. SSAR members should correct their directories accordingly. ●

New Herpetological Society Proposed

Operating currently within the New England area are three separate herpetological societies: the Massachusetts Herpetological Society which is based in Boston, the Connecticut Herpetological Society whose meetings are held at many and varied localities throughout the state and the Springfield-based Western Massachusetts Herpetological Society. Communications between the three organizations are, traditionally, poor at best. In an effort to open wide the door of communication and knowledge, a proposal has been made by Howard L. Freeman, a professor at Springfield College and member of the board of directors of the WMHS, for the organization of a more broadly-based society to be called the "NEW ENGLAND HERPETOLOGICAL SOCIETY".

The details of this proposal have not yet been finalized, but it would be hoped that the NEHS would become a grandfather to all current and future locally-based societies, augmenting and adding a cohesiveness to the efforts of these clubs.

Meetings would be held a minimum of twice a year at various suitable locations. Plans for a publication of recognized authority within the herpetological field are also being made, within which articles and notes on the ecology, taxonomy, husbandry, range extensions, etc., would be published.

Howard Freeman would appreciate hearing from any persons that would have an interest in such a society and whom may have ideas or suggestions for its formation. Write: Howard L. Freeman, Department of Biology, Springfield College, 263 Alden Stret, Springfield, Massachusetts 01109. ●

Societe Herpetologique de France (French Herpetological Society)

The French Herpetological Society (SHF) has been active since 1970. Membership includes both professional and amateur herpetologists and now totals approxmately 500 members. A quarterly internal newsletter is

published. Local and general meetings are held each year in connection with other European herpetological societies.

Current projects include accurate mapping of all French species and emphasis is put on protection of endangered species in France and overseas.

For further information and applications for membership, write to one of the SHF officials (addresses below).

SEND ALL DUES TO: Societe Herpetologique de France, 7 Quai St., Bernard 75230, Paris CEDEX FRANCE.

PRESIDENT: Dr. Guy Naulleau, Centre d'etude biologique des animaux sauvages/CNRS, 79360 Villiers en Bois.

SECRETARY: Dr. Gilbert Matz, Laboratoire de Biologie Animale, Universite d'Angers, Bd. Lavoisier 49045 Angers Cedex.

TREASURER: Dr. Jacques Castanet, Laboratoire d'Anatomie Comparee, Universite Paris VII, 2, Place Jussieu 75005 Paris.

Foreign memberships are welcome. ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Standard Common and Current Scientific Names for North American Amphibians and Reptiles (Collins, Huheey, Knight and Smith, 1978). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Department of Biology, Virginia Commonwealth University, Richmond, Virginia 23284. Short manuscripts are only acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

CAUDATA

AMBYSTOMA ANNULATUM (Ringed Salamander). USA. ARKANSAS: Montgomery Co., Big Brushy Recreation Area, 9.3 km NW Pencil Bluff. 1 April 1973. R. T. Allen and P. D. Kittle. Identified by P. D. Kittle. Univ. Ark. Mus., 76-225-1. First record for county and fourth for Ouachita Mountains (Anderson, 1965. Cat. Amer. Amph. Rept., 19.1). The specimen was discovered under leaf litter in woods dominated by Quercus spp.

Submitted by PAUL D. KITTLE, Department of Biology, Hartwick College, Oneonta, New York 13820. ●

SALIENTIA

HYLA EXIMIA (Mountain Treefrog). USA. NEW MEXICO: Catron Co: head of McKenna Creek, 14.2 km W Gila Cliff Dwellings Nat. Mon., R 15 W, 5 12 S, section 30. 11 June 1972. D. L. Hunt. New Mexico St. Univ. collection, NMSU 3685-6. Head of Little Dry (Creek), 15 KM E and 8.3 km S Glenwood, R 18 W, T 12 S, section 20. 17 July 1971. D. L. Hunt. Verified by A. H. Price. NMSU 3824. Stebbins (1966), Cochran and Goin (1970). The New Field Book of Reptiles and Amphibians, G. P. Putnam's Son, NY, 359 00.) and Duellman (1970. The Hylid Frogs of Middle America, Museum of Natural History, University of Kansas, 753 pp.) indicate this species occurs in the mountains of west-central New Mexico, but we have been unable to determine whether or not this is based on extant specimens. This species appears to be rare in New Mexico in any case, and we feel this warrants bringing the existence of these specimens to the attention of the herpetological community.

Submitted by ANDREW H. PRICE and DANE G. JOHNSON, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. ●

TESTUDINES

TRIONYX SPINIFERUS HARTWEGI (Western Spiny Softshell). USA. OKLAHOMA: Creek and Okfuskee Co: 4.8 km E Welty, Deep Fork of the Canadian River. 4 July 1977. Hank and Shawn Shannon. Webster Nat. Hist. Mus. 204-77. New county records in central park of Oklahoma range (Webb, 1970, Reptiles of Oklahoma, U. Oklahoma Press).

SERPENTES

CARPHOPHIS AMOENUS HELENAE (Midwest Worm Snake). USA. ARKANSAS: Greene Co: 8 km W Paragould, Campus Crowley's Ridge College. 15 Sept. 1977. S. M. Bounds. Crowley's Ridge Coll. Mus. Zool., CRCMZ H-022. Cross Co: Village Creek State Park. One specimen photographed and released Fall 1977, one specimen preserved Spring 1978. RF private collection. First records of this snake west of the Mississippi River (Dowling, H. G. 1957. Occ. Pap. U. Ark. Mus. 3: 1-51; Anderson, P. 1965. The reptiles of Missouri. U. Mo. Press, Columbia. 330 p.). All three specimens come from Crowley's Ridge representing localities 104 km apart; no specimens of C. a. vermis are known from this area. Additionally, all specimens examined from a few km west, in the Ozark foothills, are referable to C. a. vermis. It appears that C. a. helenae occupies at least Crowley's Ridge in the Mississippi Delta of NE Arkansas and C. a. vermis the rest of the state.

brate Collection (USAO 73). First record for country and extends range 21 km NE of nearest known locality in Comanche Co. (Webb, 1970, Reptiles of Oklahoma, Univ. Okla. Press).

Submitted by CHARLES M. MATHER, Department of Science and Mathematics, University of Science and Arts of Oklahoma, Chickasha, Oklahoma 73018.

Texas Amphibians and Reptiles: Some New Distributional Records, Part 1

The following records add to the distributional data of some species of reptiles and amphibians in Texas. These range extensions and new county records supplement those of Raun and Gehlbach (1972), Lewis (1974), Burr and Morris (1975), Hambrick (1975, 1976), Merkord (1975), Cys (1976), and Mather and Dixon (1976). Unless discussed as a range extension or a range-margin extension, specimens are exclusively new county records for the given counties. All specimens are deposited in the Texas A&I Collections, Texas A&I University. Parenthetical numbers refer to the number of individual specimens entered as a series with the same catalogue number. All identifications and verifications were made by Dr. Allan H. Chaney and the author. Nomenclature follows Conant (1975) and Collins, et al. (1978).

CAUDATA

Ambystoma tigrinum mavortium (Barred Tiger Salamander): STARR Co. TAIC-4115(14). San Isidro. May 1976. A. Ortiz. This series of specimens extends the range-margin westward in extreme south Texas from Brooks and Hidalgo counties. VAL VERDE Co. TAIC-3667(7). Bed Rock Crossing of the Pecos River, 40.2 km N Langtry. 14 April 1974. A. Chaney, et al. These specimens were introduced to this locality by sport fishermen, using the salamanders as bait; some specimens have hook-inflicted wounds on the dorsal surface of the neck. Tiger salamanders are often available at local bait stands (A. H. Chaney, pers. comm.).

Notophthalmus meridionalis meridionalis (Black-spotted Newt): NUECES Co. TAIC-3827(1). Banquete. 12 April 1975. D. McCarty.

Plethodon glutinosus glutinosus (Slimy Salamander): UVALDE Co. TAIC-1786(3). 32 km NW Uvalde on FM rd. 1051. 1 March 1969. J. Rickner, et al. This record is a range-margin extension along the Balcones Escarpment, from adjacent Real and Bandera counties.

SALIENTIA

Bufo punctatus (Red-spotted Toad): BRISCOE Co. TAIC-1650(2). 16.1 km WSW Quitaque. 4 September 1968. K. Matocha and B. Chapman.

Hypopachus variolosus (Sheep Frog): KENEDY Co. TAIC-4106(1). 30.3 km S Sarita on U.S. 77. 12 June 1977. R. Schmidt and J. Karges.

Rana catesbeiana (Bullfrog): WILLACY Co. TAIC-4114(3). 20.6 km W Raymondville o Texas 186. 12 June 1977. J. Karges and R. Schmidt. These three specimens are a range extension southward of 88 km, from the nearest county record, Kleberg Co.

TESTUDINES

Chelydra serpentina serpentina (Common Snapping Turtle): LAMPASAS Co. TAIC-2017(1). 12.8 km N Adamsville on U.S. 281. 24 August 1969. V. McDaniel and K. Matocha. MATAGORDA Co. TAIC-3621(1). 12.8 km SE Bay City. 29 March 1974. A. Chaney, et al. WALLER Co. TAIC-703(1). 8 km NW Katy. Spring, 1967. W. Kretz.

Kinosternon subrubrum hippocrepis (Mississippi Mud Turtle): COMAL Co. TAIC-2422(1). Landa Park, New Braunfels. 25 April 1971. J. Kreuz, et al. This specimen represents a range-margin extension to the west from adjacent Hays Co.

Sternothaerus odoratus (Stinkpot): BLANCO Co. TAIC-372(3). Blanco River, Blanco. 20 November 1966. A. Chaney, et al.

SAURIA

COLEONYX BREVIS (Texas Banded Gecko): DUVAL Co. TAIC-3880(1). 7.2 km S Freer on Texas 339. 29 February 1976. R. Schmidt and J. Karges. TAIC-4022(1). 10.6 km S Freer on Texas 339. 25 July 1976. J. Karges and R. Schmidt. These two specimens partially bridge the area between an isolated Kleberg Co. record and records for Webb county.

Eumeces tetragrammus brevilineatus (Short-lined Skink): LA SALLE Co. TAIC-643(1). 16.1 km SE Cotulla on FM rd. 468. 9 April 1967. A. Chaney, et al. MAVERICK Co. TAIC-2473(2). 17.7 km ESE Eagle Pass on U.S. 277. 23 April 1971. A. Chaney, et al. Eumeces tetragrammus tetragrammus (Four-lined Skink): STARR Co. TAIC-2931(1). 3.2 km W Rio Grande City. 10 March 1972. P. Villareal. The Starr county specimen is a range-margin extension west of adjacent Hidalgo county. WILLACY Co. TAIC-2748(1). Raymondville. 23 January 1972. A. Ortiz. TAIC-3206(1). San Perlita. 18 April 1972. T. Blasienz. TAIC-3207(1). San Perlita. 15 April 1972. C. Montez and R. Sanderval.

Ophisaurus attenuatus attenuatus (Western Slender Glass Lizard): JIM WELLS Co. TAIC-2823(1). Alice. 5 March 1972. I. Nava. This specimen is a range-margin extension west from Kleberg and Nueces counties. KENEDY Co. TAIC-508(1). 12.8 km S Sarita on U.S. 77. 7 October 1969. J. Rickner and M. Simons. The Kenedy county specimen is a link in the distribution gap between extreme southern Texas and northern populations.

Phrynosoma cornutum (Texas Horned Lizard): WILLACY Co. TAIC-3208(1). 1.2 km S San Perlita. 28 April 1972. R. Guzman.

Sceloporus variabilis marmoratus (Rosebelly Lizard): DIMMITT Co. TAIC-3661(1). Asherton. 13 April 1974. A. Chaney, et al.

SERPENTES

Coniophanes imperialis imperialis (Black-striped Snake): WILLACY Co. TAIC-3203(1). San Perlita. 15 May 1972. S. Llanes. TAIC-3384(1). 15.6 km WSW Raymondville on FM rd. 490. 27 April 1973. J. Richner. These two specimens are range-margin extensions northeastward from adjacent Cameron and Hildalgo counties.

Crotalus horridus (Timber Rattlesnake): MATAGORDA Co. TAIC-3955(2). 8 km N Bay City. 3 April 1976. A. Chaney, et al. WHARTON Co. TAIC-11(1). 9.6 km W Wharton on FM rd. 961. 2 June 1969. L. Orgak and M. Simons.

Drymarchon corais erebennus (Texas Indigo Snake): BROOKS Co. TAIC-846(1). S Falfurrias on U.S. 281. 13 August 1976. J. Tunnell. NUECES Co. TAIC-689(1). Bishop. 10 May 1967. M. Johnson.

Elaphe guttata emoryi (Great Plains Rat Snake): GOLIAD Co. TAIC-1753(2). 3.2 km S Goliad. 10 February 1969. J. Davis and S. Davis. TAIC-3941(1). 8 km N. Goliad. 22 May 1976. J. Karges. JIM HOGG Co. TAIC 3561(1). 4.8 km E Randado on Texas 16. 13 March 1970. R. Leal. KERR Co. TAIC-3290(1). 20.9 km S Kerrville. 28 October 1972. A. Chaney. MATAGORDA Co. TAIC-3413(1). 7.6 km NE Wadsworth on FM rd. 521. 14 April 1973. A. Chaney, et al. McMULLEN Co. TAIC-1362(1). 49.6 km S Tilden on FM rd. 624. 17 October 1969. C. Huckabee. WEBB Co. TAIC-732(1), TAIC-734(1), TAIC-1147(1), TAIC-1150(1), TAIC-1181(1), TAIC-1215(1), TAIC-2357(1). The eight specimens listed above are from several localities within the county; they confirm the existence of Elaphe guttata emoryi in Webb County as recorded by Williams, et al. (1961) and omitted by Raun and Gehlbach (1972).

Ficimia streckeri (Mexican Hooknose Snake): WILLACY Co. TAIC-4109 (1). 14.6 km W Raymondville on Texas 186. 12 June 1977. J. Karges and R. Schmidt. The specimen is a range-margin extension northeastward from Cameron Co.

Heterodon platyrhinos (Eastern Hognose Snake). LAVACA Co. TAIC-3303(1). 14.5 km N Yorktown on FM rd. 531. 10 March 1973. D. Merian. NUECES Co. TAIC-890(1). Calallen. 25 May 1960. B. Konze. TAIC-3980 (1). Port Aransas. 20 May 1976. S. Rabalais and N. Rabalais. WALLER Co. TAIC-696(1). 11.3 km N Katy. Spring, 1967. W. Kretz. WHARTON Co. TAIC-156(1). 11.6 km SE Bay City. 1 July 1969. M. Simons.

Lampropeltis calligaster calligaster (Prairie Kingsnake): NUECES Co. TAIC-665(1). S Bishop. 17 April 1967. M. Neil. This specimen is a range-margin extension southeastward from adjacent San Patricio Co. REFUGIO Co. TAIC-2680(1). 4.8 km E Refugio on FM rd. 774. 10 November 1971. T. Edwards. TAIC-4011(1). 8.5 km E Refugio on FM rd. 774. 31 July 1976. TAIC-4013(1). 12 km E Refugio on FM rd. 774. 31 July 1976. Both TAIC-4011 and TAIC-4013 were collected by R. Schmidt and J. Karges.

Lampropeltis getulus splendida (Desert Kingsnake): WEBB Co. TAIC-695(1). 16.1 km W Encinal on Texas 44. 20 April 1967. A. Chaney, et al.

Lampropeltis triangulum annulata (Mexican Milk Snake): KLEBERG Co. TAIC-278(1), TAIC-686(1), TAIC-669(1), TAIC-700(1), TAIC-790(1), TAIC-1563(1), TAIC-3788(1). The seven specimens are from several localities in Kleberg County, by several collectors.

Masticophis taeniatus schotti (Schott's Whipsnake): DUVAL Co. TAIC-2355(1). 1.6 km W Freer on Texas 59. 22 April 1971. A Chaney, et al. TAIC-3328(2). 6.9 km E Benavides on FM rd. 2295. 14 March 1973. A. Chaney, et al. Masticophis taeniatus ruthveni (Ruthven's Whipsnake). WILLACY Co. TAIC-4072(1). 8 km W Port Mansfield on Texas 186. March, 1977. A. Ortiz.

Nerodia rhombifera rhombifera (Diamondback Water Snake). KENEDY Co. TAIC-4108(1). 27 km S Sarita on U.S. 77. 12 June 1977. J. Karges and R. Schmidt.

Opheodrys aestivus (Rough Green Snake): DEWITT Co. TAIC-3643(1). Yorktown. 5 April 1974. S. Gallager.

Pituophis melanoleucus sayi (Bullsnake): DIMMITT Co. TAIC-4076(1). 12.8 km SE Catarina on U.S. 83. 22 April 1977. A. Chaney. JIM HOGG Co. TAIC-1368(1). 2.9 km NE Hebbronville on Texas 359. 10 October 1969. B. Allex, et al. MAVERICK Co. TAIC-1849(1). 32.8 km E Eagle Pass on U.S. 277. 19 April 1964. A. Chaney, et al. McMULLEN Co. TAIC-328(3), TAIC-1349(1), TAIC-1635(2), TAIC-3291(1). The seven bullsnakes were obtained from four localities in McMullen Co.

Regina rigida sinicola (Gulf Crayfish Snake): MATAGORDA Co. TAIC-3414(1). 14.7 km SE Bay City on FM rd. 2540. 14 April 1973. A. Chaney, et al. This record is an extension of the range of Regina rigida approximately 83 km to the southwest of the nearest county record, Galveston Co.

Rhinocheilus lecontei tessellatus (Texas Longnose Snake): ECTOR Co. TAIC-3526(1). Notrees. 22 July 1973. J. Rickner. McMULLEN Co. TAIC-1606(1). 30.4 km N Freer on Texas 16. 22 September 1968. J. Rickner and R. Tinnin.

Storeria dekayi texana (Texas Brown Snake): BROOKS Co. TAIC-296 (1). 0.8 km E Falfurrias on Texas 285. 20 April 1966. R. Zimmerman, et al. TAIC-1134(1). 11.3 km E Falfurrias on Texas 285. 9 October 1969. S. McMurry, et al. CALHOUN Co. TAIC-2867(1). 5.5 km N. Tivoli on Texas 35. 16 March 1972. A. Chaney, et al. TAIC-3338(1). 33.8 km NE Refugio on Texas 35. 12 April 1973. A. Chaney, et al. JACKSON Co. TAIC 3936(1). 8 km N Ganado. 16 May 1976. R. Schmidt and J. Karges. JIM WELLS Co. TAIC-2824(1). Alice. 5 March 1972. I. Nava. KIMBLE Co. TAIC-3187(1). Near Junction. 16 April 1972. A. Chaney, et al. WILLACY Co. TAIC-617(1). 5.8 km N Raymondville on U.S. 77. 1 March 1967. D. Mahoney. TAIC-2797(1). 2.1 km N Raymondville on U.S. 77. 20 February 1972. Texas A&I University herpetology class. TAIC-2889(1). 1.4 km S Kenedy Co./Willacy Co. border, on U.S. 77. 14 March 1972. Texas A&I University herpetology class.

Tropidoclonion lineatus texanum (Texas Lined Snake): CORYELL Co. TAIC-3983(1). Fort Hood Army Base. 18 June 1976. T. Edwards.

I express my gratitude to Dr. Allan H. Chaney for allowing me access to the Texas A&I Collections, and for offering suggestions. I also thank Mr. Richard R. Schmidt for participation in the field, and Mrs. Linda M. Scheck for typing the manuscript.

News Notes

NEW GERMAN HERP BOOK

A new book, written in German, on snakes in captivity has just be released by Kosmos Franckh, Stuttgart. Entitled Schlangen im Terrarium and written by Werner Frank, this 64 page publication contains much valuable information about maintenance of snakes in captivity, and contains numerous, excellent color photographs. The book is dated 1978 and is available for DM 8.80 from: Franckh-Kosmos, Pfizerstrasse 5-7, 7000 Stuttgart 1, Germany.

NEW HERP DICTIONARY

A dictionary for the specialist in anatomy and herpetology, by George J. Jacobs, has been published by the Smithsonian Institution Press. This English-Russian: Russian-English dictionary is double columned, 9 x 10" and is 48 pages long (over 4600 Russian words) with a saddle stitched paper back for high readability and ease of use.

To purchase a copy, send $4.75 to Smithsonian Institution Press, Box 1579, Washington, D. C. 20560.

(Currently being reviewed for H.R.-ed.)

SSAR AWARD FOR BEST STUDENT JOURNAL PAPER

The Society for the Study of Amphibians and Reptiles awards an annual prize of $100 for the most significant student paper published in each volume of the Journal of Herpetology. Papers must be submitted to the Editor for publication within one year of the author's having been a student at an accredited school (elementary, secondary or university level). Unlike awards for oral presentations, which require the presence of the person at a particular meeting site in order to compete, this prize is open to students throughout the world. Papers are judged by a committee of five persons, international in composition. The Editor must be notified of the student status of the author when the paper is accepted for publication. The award is presented at the Society's Annual Meeting, and it is hoped that each year recipients will be present to accept the award.

THE THEODORE ROOSEVELT MEMORIAL FUND

The Theodore Roosevelt Memorial Fund provides financial assistance to individuals (especially graduate students and persons with recent graduate degrees) conducting research in North America on any phase of wildlife conservation or natural history related to the activities of the American Museum of Natural History. Grants are usually kept to small sums of not more than several hundred dollars. Most awards support field work, and funds are not made available for salaries or for the purchase of non-expendable equipment. Address requests for application forms and all correspondence to: Theodore Roosevelt Memorial Fund, The American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024. Deadline for applications is 15 February.

NEW TORTOISE VOLUME

Attention is called to a volume entitled Desert Tortoise Council -- Proceedings of 1977 Symposium. Thirteen contributed papers concern various facets of tortoise ecology, while the area reports generally involve tortoise conservation and habitat management. Together, they provide a wealth of information on the tortoise in its environs. Copies are available for $5.00 each from:

Desert Tortoise Council
1835 Klauber Avenue
San Diego, California 92114

Make checks payable to Desert Tortoise Council.

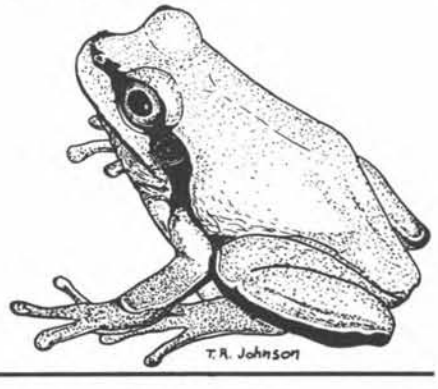
NEW CROCODILIAN BOOK

Bestimmen von Krokodilen und ihrer Haute, by Heinz Wermuth and Karlheinz Funchs. 1978. 100 pp. Soft cover. Available for DM 29 from: Gustav Fischer Verlag, D-7000 Stuttgart 72, Postfach 720143, Germany.

This compact, attractive little volume contains a checklist, key, and well-written species accounts of the crocodilians of the world. Each species account contains black-and-white illustrations and a range map. A must for crocodile-oriented biologists.

GECKO INFORMATION REQUESTED

Research on Coleonyx variegatus indicates that individuals select a certain site in which to defecate and return to this area on subsequent nights. I am trying to determine the extent of this behavior in gekkonid lizards. Arboreal species may coincidentally aggregate fecal material while at a favorite perch site. This differs from purposeful aggregation as exhibited by Coleonyx. Any observations on gekkonid lizards, whether demonstrating fecal aggregation or not, would be greatly appreciated. Please contact James D. Jenkins, Department of Zoology, Arizona State University, Tempe, Arizona 85281.



GAMBELIA PRESERVE PLANNED

The Golden Valley Ecological Society (P. O. Box 709, Clovis, California 93613) is seeking to purchase and now in escrow as a preserve for Blunt-nosed leopard lizards. They need contributions for purchase funds urgently. Contributions are tax deductible (pending final federal ruling--state tax exempt status approved) and would be greatly appreciated.

HR 9(3) ERRATA

Page 109, column 1, para. 2, lin 4: C. rotalus should read Crotalus.

Page 109, column 1, para. 3, line 6: masticophis should read Masticophis.

LETTER TO THE EDITOR REGARDING COMMON NAMES LIST

The recently published "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (1978, SSAR Herpetological Circular No. 7) stated that it followed, with few exceptions, the common names used by Stebbins (1966, A Field Guide to Western Reptiles and Amphibians) and Conant (1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America). In point of fact, the SSAR publication diverges from the common names used by Stebbins and Conant for no fewer than 146 taxa, divergences not required by taxonomic changes. In most instances the change consists of dropping an -ed ending to convert a hyphenated, compound participial adjective into a nonhyphenated, compound noun form, e.g., the "Short-headed Garter Snake" becomes the "Shorthead Garter Snake."

We strenuously object to these changes for the following reasons: 1) They violate the spirit of article 4d in the Harbrace College Handbook, which states in effect that the use of noun forms as adjectives should be avoided when they are either awkward or ambiguous and appropriate adjectives are available. To our ears many of the new names do sound awkward, a few could be ambiguous to the nonherpetologist (is a Blackhead Snake covered with dark spots that resemble blackheads?), and for each of them an appropriate adjective does exist. We believe the scientific community should support proper usage of the English language, not contribute to its deterioration. 2) The changes are inconsistently applied. The "Black-striped Snake" remains unchanged, while two of the ribbon snakes become the "Redstripe Ribbon Snake" and the "Bluestripe Ribbon Snake," respectively. The "Short-tailed Snake" remains unchanged, while the "Flatheaded Snake" becomes the "Flathead Snake." Similar examples are legion. 3) No rationale is presented for any of the changes; hence they appear to have been made solely for the sake of change.

The Committee on Common and Scientific Names strongly urged that everyone use their standardized list of common names in all conceivable circumstances in order to stabilize and clarify the use of these names by the herpetological community and the general public. Inasmuch as many of the changes they have proposed are grammatically unsound, inconsistently applied, and, as far as we can determine, unnecessary, we strongly urge that the herpetological community reject these changes and continue to follow the common names used by Stebbins (1966) and by Conant (1975) until such time as the Committee on Common and Scientific Names issues a revised list that eliminates, or at least comes to grips with, these objections.

DOUGLAS A. ROSSMAN, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893; HENRY R. MUSHINSKY, Department of Zoology and Physiology, Louisiana State University, Baton Rouge, Louisiana 70893; and HERBERT C. DESSAUER, Department of Biochemistry, Louisiana State University, Medical Center, New Orleans, Louisiana 70112.

"COMMON NAMES" -- A DIFFERENT VIEWPOINT

I find myself in the embarassing position of agreeing somewhat more closely with the critics (Rossman et al., 1978) of a Committee Report (Collins et al., 1978a) bearing my name than with the response authorized by a majority of that Committee (Collins et al., 1978b). However, my disagreement is limited to certain select points. For example, I think that, in general, the changes made by the Committee were, indeed, conservative and, although I may have reservations about particular choices, I think that on the whole the current list is a good one, otherwise I could not have agreed to have it appear under my name. With the exception of the specific points listed below, I urge that the list be used, until a better version can be produced.

The one point on which I agree with Rossman et al. (1978) and others (personal communication) is in the correct English grammatical usage of hypenated, past-participial adjectives (e.g., Black-headed Snake) vs. a supposed "noun-in-apposition" construction (e.g., Blackhead Snake). Although the only reference cited in this matter (Bailey et al., 1970) states that the "spottail shiner" and "soupfin shark" illustrate "Compounded modifying words, including paired structures, (which) should usually be treated as nouns in apposition...", (emphasis mine) this is an unfortunate oversimplification and relaxation of usage. A true noun in apposition such as: "Walter Washington, first mayor of Washington, DC, requested..." or "Zoologist John Q. Doe, discoverer and describer of over 155 taxa of amphibians and reptiles, claimed..." involves a construction which the appositive fragment, set off by commas, is an exact equivalent (not a modifier) of the noun to which it is in apposition. Since one can use titles (in the broadest sense of the word) preceding a noun which they modify: "Mayor Walter Washington requested ...", some are tempted to use such noun-adjectives and call them "appositives". This leads to such clumsy constructions as: "Discoverer-and describer-of-over-150-taxa-of-amphibians-and-reptiles-zoologist John Q. Doe claimed..."

By analogy, one can thus refer to Muscivora forficata as the Scissor-tailed Flycatcher (Peterson, 1947; Bull and Farrand, 1977), or as is done by ranchers of the southwest, truly using a common name and a descriptive noun , call it a "Scissortail" (personal observation). This presents no problem. But the noneuphonic, nongrammatical, nonlogical "Scissortail Flycatcher" or "Blackhead Snake" strikes my ear with the same dissonance as "A beautiful, blue-eye woman; a handsome, redhair man, or: Look at the spot Dalmation dog!"

Having made what I hope is a convincing argument to the reader that some semblance of logic and grammar be retained in the English language wherever possible, I should like to make a second, seemingly orthogonal argument: It really doesn't make any difference from the point of view of communications whether one follows Collins et al., (1978a) or Rossman et al. (1978). Although the "Blackhead Snake" as used by a majority of the Committee grates on my sensibilities, I have no difficulty recognizing that a member of the genus Tantilla is involved, nor does anyone reading my preferred usage. Unlike scientific nomenclature where, for purposes of preciseness, certitude, and priority, the changing of a single letter results in a completely different epithet, the usage of common, or English names does not, nor should it, require such legalisms. Thus, I regret what I perceive to be a trend towards expecting absolute conformity in the use of an "official" list of common names: The use of Black-headed vs. Blackhead is inconsequential (preservation of English as a logical, informative language aside) compared to the usage of Uma vs. Uta for certain western North American lizards. The true difficulties in communication will arise if Author A uses Tantilla = Black-headed Snakes, Author B uses Tantilla = Crowned Snakes, and Author C uses Tantilla = Black-headed and Crowned Snakes. (An aside: Why not the Crown Snake?

Probably because everyone's limit of noneuphonism is reached eventually and constructions such as a Crown Snake, a Birdvoice Treefrog, and a spot dog sound ludicrous to all.) Good nomenclature should provide clarity and, much more important for scientific than popular nomenclature, stability. Compatibility and consistency need not necessitate absolute congruence. Although scientific nomenclature is, necessarily, belabored by the requisites of orthography and priority, the use of English names is not so encumbered; may I request more good judgment and flexibility in place of absolute conformity?

I have a third request. None of the names on the list of "common" names would be at all common in Mexico or, if that be objected to as extralimital, in parts of Quebec. Furthermore, I believe that residents of the southern Appalachians would recognize only about one-quarter of the "common" names given for the Great Smoky Mountains (Huheey and Stupka, 1968). As demonstrated in two papers recently called to my attention (Parkes, 1975; 1978), what we are really discussing here are standardized English names.

It may appear incongruous for a member of the Committee on Common and Scientific Names of the SSAR to appear to dissent from a report of that Committee. This is not the case. I believe the report (Collins, et al., 1978a) is a good one, and in those several instances in which I disagreed with the majority, I allowed my opinions to be overruled in deference to my respect for the professional opinions of the others, and my feeling that, for the reasons cited above, one should never consider a list of English names to be engraved upon stone, but as a flexible, constantly improvable, and currently useful list. It is with the hope that such improvement may ever be forthcoming that I offer my dissent. I would plead that all of those interested in the subject of English or common names retain open minds--maximum communication is the ultimate goal, not any one person's (including my own) perception of the "truth".

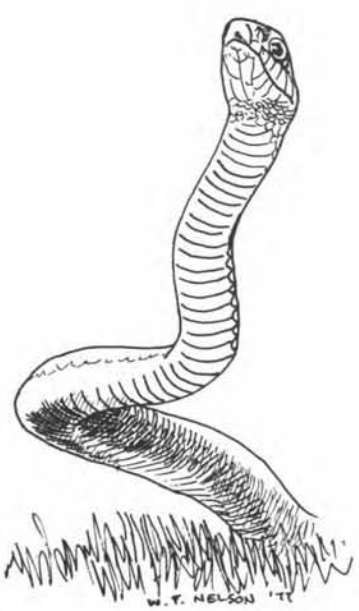
THE RATIONALE FOR NAME-CHANGES IN THE COMMON NAMES LIST

The issues raised by Rossman, et al. in the critique of the SSAR "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" require explanations that no doubt should have been given in the introduction to our list. They are belatedly provided here.

First, although "no fewer than 146 taxa" have been assigned altered common names by the SSAR Committee, this does not appear to be excessive when compared to the total number of names (over 1,200) which appear in the list. A twelve percent divergence from the names used by Conant and Stebbins in their Field Guides is not an extensive rearrangement.



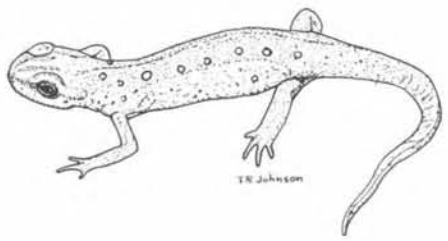
Second, although we cannot argue against rules or recommendations made in the Harbrace College Handbook, the use of non-hyphenated, compound nouns is not illegal, and is, in fact, more concise and more easily used in speaking. Common names are used by persons not familiar with scientific names, and will be adopted only if easily understood and easily spoken. The English languate is not inflexible, and allows for such alterations to permit ease of use.

Third, the common name changes involving elimination of the hyphen and -ed ending are very consistently applied. Wherever previously hyphenated common names represented an unpaired structure (i.e., head, throat, belly, tail, mouth, nose, back, chin, skin, mask, hood) or a feature appearing singularly on a taxa (i.e., a single stripe), the hyphen and -ed ending were eliminated. The only exceptions (conformant with the Harbrace College Handbook) to this convention (involving five names out of 1,208) were four which would have produced a difficult double consonant (tt) and Birdvoiced Treefrog. Voice was not readily assignable as a singular structure and was retained in its original form. The -ed ending only adds length to a common name, and the use of a hyphen adds to the possibility of mistakes occurring in transliteration.

Fourth, the rationale to alter common names was based on 1) a desire to produce more concise (and, hence, more easily used) common names, and 2) recognition that other common name lists are implementing the alterations we employed (see A List of Common and Scientific Names of Fishes, AFS Spec. Pub. 6, third edition, 1970).

Finally, the SSAR Common Names List, when considered in its entirety, must surely be considered conservative and conventional when compared with the 1956 ASIH list, and, thus, would hopefully receive reasonable acceptance by the herpetological community. As generally stated in the introduction of the SSAR Common Names List, we again strongly urge that all persons use the proposed names in the interest of stability and clarity.

JOSEPH T. COLLINS, JAMES L. KNIGHT, and HOBART M. SMITH, SSAR Committee on Common and Scientific Names. ●



Current Literature

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

A new feature of Current Literature is the inclusion of senior author addresses. Although only a small portion of the citations have the addresses included in this issue, it is a goal to publish addresses for a majority of the citations for Current Literature in 1979.
